Ethyl methyl ether and methyl phenyl ether are nonsymmetric molecules. This is because the R groups attached to the oxygen atom are different. When both R groups are the same, the ether is symmetric. The same rules apply when naming symmetric ethers with the IUPAC system as shown in the examples below. The common names of symmetric ethers use the prefix *di-*. Sometimes, however, the prefix *di-* is dropped and a compound such as diethyl ether is simply called ethyl ether.

Ethoxyethane (diethyl ether) — Phenoxybenzene (diphenyl ether)

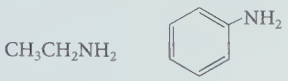
Diethyl ether was the first reliable general anesthetic. Doctors used it for more than a century. However, because diethyl ether is highly flammable and often causes nausea, it was eventually replaced by other anesthetics such as isoflurane shown in Figure 23.7. Diphenyl ether is used in the manufacture of perfumes and soaps for its characteristic geranium smell.

Ethers usually have lower boiling points than alcohols of comparable molar mass, but higher boiling points than comparable hydrocarbons and halocarbons. Unlike alcohols, ethers are not capable of forming hydrogen bonds with other ether molecules. The oxygen atom in an ether is a hydrogen acceptor. But recall that ethers have no hydroxy hydrogen atoms to donate in hydrogen bonding. Ethers can, however, form hydrogen bonds with water. So ethers are more soluble in water than hydrocarbons and halocarbons. Ethers are less soluble in water than alcohols because they form fewer hydrogen bonds than alcohols do when interacting with water.

Professional Development Note

Ethers as Solvents

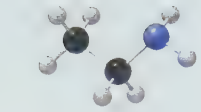
Ethers are used as nonpolar solvents to extract natural products such as lipids. Low molar-mass ethers are partially soluble in water due to the ability of the oxygen atoms in the ether functional groups to form hydrogen bonds with water molecules. Solubility in water decreases as the mass of the carbon groups increases.



810 Chapter 23 • Lesson 2

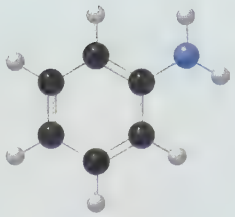
Amines

What is the general formula of an amine?



An **amine** is an organic compound in which nitrogen is bonded to a carbon group. Amines are similar to ammonia (NH_3). When one, two, or three of the hydrogens in ammonia are replaced by carbon groups, the compound is classified as an amine. **The general formula of an amine is RNH_2, R_2NH, or R_3N.** Amines can be classified according to the number of R groups attached to the nitrogen atom. An amine with the general formula RNH_2 is a primary amine because one R group is attached to the nitrogen atom. Amines with two and three R groups attached to the nitrogen atom are secondary and tertiary amines, respectively.

The IUPAC system for naming primary amines is similar to that of alcohols. The *-e* ending of the parent hydrocarbon is changed to *-amine*. For example, CH_3NH_2 is named methanamine. The common names of primary amines are similar to the IUPAC names. The alkyl or aryl group is named and followed by *-amine*. The common name for methanamine is methylamine. Figure 23.8 shows ball-and-stick models of the two simple primary amines ethanamine and benzenamine.



Ethanamine (ethylamine) Benzenamine (phenylamine)

Like alcohols, primary amines form intermolecular hydrogen bonds. Because nitrogen is less electronegative than oxygen, the hydrogen bonds in amines are not as strong as those of alcohols. As a result, primary amines have lower boiling points than alcohols with a comparable number of carbons. Amines can also hydrogen bond with water. So smaller amines are soluble in water, but as the number of carbons increase, the solubility in water decreases.

Ethanamine

Benzenamine

Figure 23.8 Primary Amines Ethanamine is used to make plastics, pharmaceuticals, and pesticides. Benzenamine is used to make furniture foam and some of the dyes that give clothing their colors.
Explain ***Why are these compounds primary amines?***

23.2 LessonCheck

9. Review What is the general formula of an alcohol?

10. Review How are addition reactions commonly used in organic chemistry?

11. Describe Write the general formula of an ether.

12. List What are three possible general formulas of an amine?

13. Identify Write the IUPAC and common names of each compound below.

a. $CH_3CH_2\underset{\displaystyle OH}{\underset{|}{C}}HCH_3$

b. $CH_3CH_2CH_2NH_2$

c. $CH_3CH_2CH_2OCH_2CH_2CH_2CH_3$

14. Predict Give the structure for the expected organic product from each of the following addition reactions.

a. $CH_3CH{=}CHCH_3 + H_2O \xrightarrow[100°C]{H^+}$

b. $CH_2{=}CHCH_3 + Cl_2 \longrightarrow$

c. $CH_3CH{=}CHCH_3 + HBr \longrightarrow$

d. $CH_3CH{=}CHCH_3 + H_2 \xrightarrow{\text{catalyst}}$

BIG IDEA REACTIONS

15. Write a short paragraph in which you compare and contrast substitution reactions and addition reactions. Include at least two examples of each reaction type, and describe your examples with balanced equations.

Lesson Check Answers

9. ROH

10. to introduce new functional groups to organic molecules and to convert alkenes to alkanes

11. ROR

12. RNH_2, R_2NH, R_3N

13. a. 2-butanol, *sec*-butyl alcohol

b. propanamine, propylamine

c. propoxybutane, butyl propyl ether

14. a. $CH_3CH_2\underset{\displaystyle OH}{\underset{|}{C}}HCH_3$

b. $CH_2\underset{\displaystyle Cl}{\underset{|}{C}}HCH_2\underset{\displaystyle Cl}{\underset{|}{C}}HCH_3$

c. $CH_3CH_2\underset{\displaystyle Br}{\underset{|}{C}}HCH_3$

d. $CH_3CH_2CH_2CH_3$

15. BIG IDEA Students' paragraphs should mention that substitution reactions involve atom substitution, and addition reactions involve atom addition. Check students' example reactions.

Explain

Amines

MAKE A CONNECTION Explain that amines are known for their often unpleasant odor. Ask students if they are familiar with the odor of decomposing meat. Two of the compounds responsible for this odor are amines, and are appropriately named putrescine ($H_2N(CH_2)_4NH_2$) and cadaverine ($H_2N(CH_2)_5NH_2$). Point out the relationship between the name *putrescine* and the word *putrid*, and the name *cadaverine* and the word *cadaver*. Draw the structures of the two compounds on the board and challenge students to determine the IUPAC names for each. *(putrescine: 1,4-butanediamine; cadaverine: 1,5-pentanediamine)*

Evaluate

Informal Assessment

Have students draw the structural formulas for 3-pentanol, 2-methyl-2-butanol, 1-heptanol, ethyl propyl ether, and diphenyl ether. Have them classify each alcohol as primary, secondary, or tertiary. Have students name and describe a chemical test for unsaturation with an organic molecule, and write the chemical equation for the reaction. Write the structure of 2-butanol on the board. **Ask** What reactants could a chemist use to prepare this compound? *(2-butene and aqueous acid)* Then have students complete the 23.2 Lesson Check.

Reteach

Review the lesson and clarify that the two atoms being added to double-bonded carbons in an alkene can be identical or they can be different. The atoms added during hydrogenation are the same. Make sure students understand that the atoms added are different when HCl reacts with an alkene to produce an alkyl chloride or when water and an alkene react to produce an alcohol.

Answers

FIGURE 23.7 nonsymmetric

Aldehydes and Ketones

What structural characteristic do an aldehyde and a ketone share?

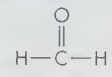
Remember that in an alcohol, an oxygen atom is bonded to a carbon group and a hydrogen atom. In an ether, an oxygen atom is bonded to two carbon groups. An oxygen atom can also be bonded to a single carbon atom by a double covalent bond. Such an arrangement is called a carbonyl group. A **carbonyl group** is a functional group with the general structure C=O.

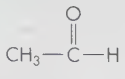
The C=O functional group is present in aldehydes and ketones. An **aldehyde** is an organic compound in which the carbon of the carbonyl group is joined to at least one hydrogen. The general formula of an aldehyde is RCHO. A **ketone** is an organic compound in which the carbon of the carbonyl group is joined to two other carbons. The general formula of a ketone is RCOR. The structures of an aldehyde and a ketone are summarized below.

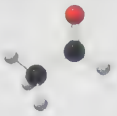
The IUPAC system may be used for naming aldehydes and ketones. For either class of compounds, first identify the longest carbon chain that contains the carbonyl group. Replace the *-e* ending of the parent structure with *-al* to designate an aldehyde. In the IUPAC system, the continuous-chain aldehydes are named methanal, ethanal, propanal, butanal, and so forth.

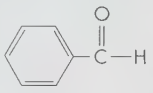
Ketones are named by changing the ending of the longest continuous carbon chain that contains the carbonyl group from *-e* to *-one*. If the carbonyl group of a ketone could occur at more than one place on the chain, then its position is designated by the lowest possible number. Table 23.5 illustrates the naming of some common aldehydes and ketones.

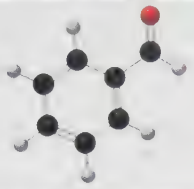
Focus on ELL

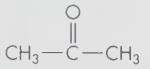


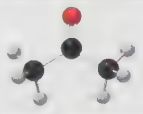


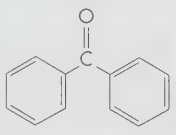


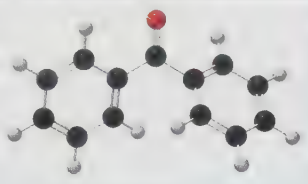












1 CONTENT AND LANGUAGE Write the lesson objectives on the board, highlighting key terms in each objective. Provide students with a graphic organizer such as a Venn diagram so that they can compare and contrast aldehydes and ketones.

2 FRONTLOAD THE LESSON Divide the class into four groups, one for each key question. Have one group member read the question aloud slowly. The group should predict the answer and then try to find the answer by previewing the lesson. Ask all groups to present their findings to the class.

3 COMPREHENSIBLE INPUT Use ball-and-stick models to demonstrate key functional groups and reactions in the text. Have students view the Kinetic Art animation of oxidation reactions to supplement the discussion of the Oxidation-Reduction section.

Table 23.5

Some Common Aldehydes and Ketones

Compound type	IUPAC name (common name)	Structural formula	Ball-and-stick model
Aldehyde	Methanal (formaldehyde)		
Aldehyde	Ethanal (acetaldehyde)		
Aldehyde	Benzaldehyde (benzaldehyde)		
Ketone	Propanone (acetone)		
Ketone	Diphenylmethanone (benzophenone)		

Uses of Aldehydes and Ketones The simplest aldehyde is methanal (HCHO), also called formaldehyde. Methanal is very important industrially. Its greatest use is in the manufacture of synthetic resins. Methanal is usually available as a 40% aqueous solution, known as formalin. Formalin can be used to preserve biological specimens. The methanal in solution combines with protein in tissues to make the tissues hard and insoluble in water. This prevents the specimen from decaying.

The most common industrial ketone is propanone, also called acetone. Propanone is a colorless, volatile liquid that boils at 56°C. Propanone is used in industry as a solvent for resins, plastics, and varnishes. Many nail-polish removers contain propanone, too.

Professional Development Note

Vanilla Beans

Vanilla flavoring comes from the seed capsules, called "beans," of several species of orchid of the genus *Vanilla*. The capsules are collected, boiled, dried, and cured to produce the long, thin, brown bean-like pods that are familiar to cooks everywhere. The vanilla orchid was first used as a flavoring by the Aztecs and the Mayans in Mexico and Central America for their *xocolatl* (chocolate) drinks. Due to advances in pollination techniques, most of the natural vanilla produced today comes from Madagascar, Reunion Island, and Tahiti rather than from Central America.

STRATEGY Have students write the general formula for an alcohol and an ether. As they read about aldehydes, ketones, and carboxylic acids, have them write those general formulas and compare them with the formulas of alcohols and ethers.

Explain

Aldehydes and Ketones

USE VISUALS Have students examine Table 23.5. Pronounce the IUPAC and the common name for each compound. **Ask** Are you familiar with any of these compounds? If so, in what respect? *(Answers will vary.)* Discuss how these compounds are named. Explain that the difference between an aldehyde and a ketone lies in whether a hydrogen atom is attached to the carbonyl group. Display the table using a transparency and overhead projector. Point out that in ketones, as in ethers, the functional group lies between two R groups. Except for methanal, the carbonyl group in aldehydes is attached to one R group and one hydrogen atom.

Explore

Class Activity

Have students gently sniff the contents of labeled test tubes containing small amounts of vanillin, isopentyl acetate, and benzaldehyde. **Ask** Which odor is that of vanilla ice cream? *(vanillin)* Bananas? *(isopentyl acetate)* Maraschino cherries? *(benzaldehyde)* Write structures for the compounds on the board. Refer to Table 23.5 for benzaldehyde and vanillin; isopentyl acetate is $CH_3COOCH_2CH_2CH(CH_3)_2$. Explain that compounds with carbonyl groups account for the odor and taste of many foods.

MAKING CONNECTIONS Explain that isopentyl acetate is referred to as banana oil, due to its banana-like flavor and smell. Mention to students that this compound was first discovered as one of the alarm pheromones of honeybees. Later it was discovered in yellow passion fruits, pears, and apples.

Explore

Class Activity

Many students may find it helpful in understanding the differences between aldehydes and ketones if they build models of compounds containing these functional groups. Have students make models of propanal, propanone, and propanoic acid. Have them examine their models and make comparisons. If model-building kits are not available, toothpicks and gumdrops or marshmallows can be used. Direct students not to eat gumdrops or marshmallows used in model building.

Explain

START A CONVERSATION Explain that many familiar smells and flavors come from organic compounds. For example, many ketones and aldehydes, particularly those with high molar masses, have fragrant odors. **Ask** What are some functional groups other than aldehydes and ketones that can have an effect on the particular odor of an organic compound? *(alcohols, esters, amines)* Have students name some of their favorite scents. **Ask** What are the natural sources of these perfumes? *(animal oils, plant extracts)* Explain that perfume makers usually combine many different compounds to create a complex scent. Although these compounds may come from animal oils and plant extracts, they can be synthesized artificially. Citral, found in roses and citrus fruits, is an aldehyde. Civetone, the odor of musk, is a ketone.

USE VISUALS Direct students' attention to Table 23.6. Ask students to think of some examples of simple organic molecules that contain carbonyl groups. Have them write the structures and build models of these molecules. **Ask** What are some structural features of carbonyl-containing molecules? *(Carbonyl groups display trigonal planar geometry.)* Point out that a carbonyl carbon represents the positive center of aldehydes and ketones and that an oxygen atom represents the negative center. Discuss the types of intermolecular forces operating between the functional groups in aldehydes and ketones. **Ask** How does the shape of a molecule affect the strength of intermolecular attractions? *(If the shape causes bond polarities within the molecule to be unbalanced, the molecule is usually polar, and intermolecular forces will be stronger than if the molecule were nonpolar.)*

Virtual Lab **InterpretGraphs**

Some Organic Compounds with Three Carbons

Compound	Formula	Boiling point (°C)	Primary intermolecular interactions
Propane	$CH_3CH_2CH_3$	−42	Dispersion forces
Propanal	CH_3CH_2CHO	49	Polar-polar interactions
Propanone	CH_3COCH_3	56	Polar-polar interactions
1-Propanol	$CH_3CH_2CH_2OH$	97	Hydrogen bonding

Table 23.6 These four organic compounds have the same number of carbon atoms. Yet their boiling points are different.
a. Classify Determine the type of each organic compound.
b. Compare Use your knowledge of intermolecular interactions to explain the similarities and differences in the boiling points of the four compounds.

A wide variety of aldehydes and ketones have been isolated from plants and animals. Many of them, particularly those with high molar masses, have fragrant odors. They are usually known by their common names, which can indicate their natural sources or perhaps a characteristic property. Benzaldehyde is the simplest aromatic aldehyde. It's also known as oil of bitter almond because it is largely responsible for the taste and aroma of almonds. Many flavoring agents, including vanilla bean extract and the cinnamon sticks shown in Figure 23.9, contain aromatic aldehydes.

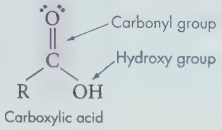
Figure 23.9 Cinnamaldehyde The cinnamon sticks in this drink contain an aldehyde with the common name cinnamaldehyde.

Properties of Aldehydes and Ketones Aldehydes and ketones cannot form intermolecular hydrogen bonds because they lack —OH and —NH groups. Consequently, they have boiling points that are lower than those of corresponding alcohols. Aldehydes and ketones can attract each other, however, through polar–polar interactions of their carbonyl groups. As a result, their boiling points are higher than those of the corresponding alkanes. These attractive forces account for the fact that nearly all aldehydes and ketones are either liquids or solids at room temperature. The exception is methanal, which is a gas. Table 23.6 compares the boiling points of an alkane, an aldehyde, a ketone, and an alcohol with the same number of carbon atoms.

Aldehydes and ketones can form weak hydrogen bonds between the carbonyl oxygen and the hydrogen atoms of water. The lower members of the series—up to three carbons—are soluble in water in all proportions. As the length of the hydrocarbon chain increases above four, however, water solubility decreases. When the carbon chain exceeds five or six carbons, the solubility of both aldehydes and ketones is very low. As might be expected, all aldehydes and ketones are soluble in nonpolar solvents.

Differentiated Instruction

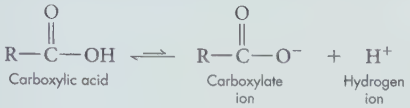
LPR LESS PROFICIENT READERS Write the general structures of an aldehyde, a ketone, a carboxylic acid, and an ester on the board. Have students copy the structures in their notebooks, and label the carbonyl groups, hydroxy groups, aliphatic groups, and aryl groups. Have them indicate whether each structure is an aldehyde, ketone, ester, or carboxylic acid.



ELL ENGLISH LANGUAGE LEARNERS Arrange students in several small topic circles with proficient students in each group. Have them discuss aldehydes and ketones in a factual, detailed progression. Ask each group to summarize their discussion for you as you circulate between groups to assess understanding and correct misconceptions.

L3 ADVANCED STUDENTS Have students study the structure of cinnamaldehyde and other carbonyl-containing compounds that have carbon-carbon bonds conjugated with a carbon-oxygen double bond. Have students consider how the location of a carbonyl group next to an alkene group affects the stability of the molecule through resonance.

Carboxylic Acids



What is the general formula of a carboxylic acid?

A **carboxyl group** is a functional group that consists of a carbonyl group attached to a hydroxy group. It can be written as —COOH or —CO_2H.
A **carboxylic acid** is an organic compound with a carboxyl group.
The general formula of a carboxylic acid is RCOOH.

Carboxylic acid

As you may have guessed from their name, carboxylic acids are acidic. Carboxylic acids are considered weak acids because they ionize weakly in solution. In water, they can lose a hydrogen ion and form a carboxylate ion, as shown in the following reaction.

In the IUPAC system, carboxylic acids are named by replacing the *-e* ending of the parent structure with the ending *-oic acid*. Remember, the parent hydrocarbon of a carboxylic acid is the longest continuous carbon chain containing the carboxyl group. So, for example, the carboxylic acid CH_3COOH is named ethanoic acid. Figure 23.10 shows the ball-and-stick model of ethanoic acid. Table 23.7 lists the names and formulas of some common saturated aliphatic carboxylic acids.

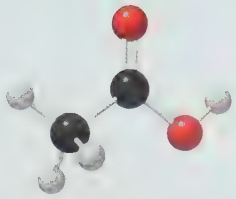


Figure 23.10 Ethanoic Acid Ethanoic acid is a simple carboxylic acid. It is a colorless, volatile liquid. **Identify** ***What R group is attached to the carboxyl group in ethanoic acid?***

Table 23.7

Some Saturated Aliphatic Carboxylic Acids

Molecular formula	Carbon atoms	IUPAC name	Common name	Melting point (°C)
HCOOH	1	Methanoic acid	Formic acid	8
CH_3COOH	2	Ethanoic acid	Acetic acid	17
CH_3CH_2COOH	3	Propanoic acid	Propionic acid	–22
$CH_3(CH_2)_2COOH$	4	Butanoic acid	Butyric acid	–6
$CH_3(CH_2)_4COOH$	6	Hexanoic acid	Caproic acid	–3
$CH_3(CH_2)_6COOH$	8	Octanoic acid	Caprylic acid	16
$CH_3(CH_2)_8COOH$	10	Decanoic acid	Capric acid	31
$CH_3(CH_2)_{10}COOH$	12	Dodecanoic acid	Lauric acid	44
$CH_3(CH_2)_{12}COOH$	14	Tetradecanoic acid	Myristic acid	58
$CH_3(CH_2)_{14}COOH$	16	Hexadecanoic acid	Palmitic acid	63
$CH_3(CH_2)_{16}COOH$	18	Octadecanoic acid	Stearic acid	70

UbD Check for Understanding

What structural characteristics do an aldehyde and a ketone share?

Have students complete the following sentence:

The main structural difference between and aldehyde and a ketone is that in an aldehyde the carbon of the carbonyl group is joined to at least one _____, whereas in a ketone the carbon of the carbonyl group is joined to two _____.

(hydrogen; carbons)

ADJUST INSTRUCTION If students are having difficulty completing the sentence, briefly review the text leading up to Table 23.5. Then have students repeat the exercise.

Explain

Carboxylic Acids

START A CONVERSATION Write the structural formula for a carboxylic acid on the board or overhead projector. **Ask** What functional groups are present, and what characteristics would you expect the molecule to have? *(Students should recognize the hydroxy and carbonyl groups and may suggest that the molecule would have properties of both an alcohol and an aldehyde.)* **Ask** Why are carboxylic acids considered to be acids? *(They contain an ionizable proton.)* Explain that the presence of the double-bonded oxygen weakens the bond between the other oxygen atom and the hydrogen atom bonded to it, so that the hydrogen can ionize easily. Point out that the overall functional group is called a carboxyl group and the molecule containing it is called a carboxylic acid.

USE VISUALS Use an overhead projector to display a transparency of Table 23.7. Discuss the IUPAC rules for naming carboxylic acids. Remind students that the systematic names are derived from the parent alkanes. Discuss the basis for the observed trends in physical properties for the homologous series of aliphatic carboxylic acids. **Ask** What is the name of an aliphatic carboxylic acid that is a solid at room temperature? *(Answers will vary, but should be restricted to those acids with melting points higher than 25°C.)* **Ask** What is the name of an aliphatic carboxylic acid that is a liquid at room temperature? *(Answers will vary, but should be restricted to those acids with melting points lower than 25°C.)* **Ask** What is the common name of an 18-carbon aliphatic carboxylic acid? *(stearic acid)*

Extend

Have students consider why carboxylic acids are considered weak acids. Write the chemical equation for the ionization of dilute aqueous ethanoic acid on the board. Point out that the acid is only partly ionized at equilibrium. Challenge students to write the equilibrium constant expression for the reaction shown. Then have them write the chemical equation for the ionization of propanoic acid.

Answers

INTERPRET DATA

a. propane, hydrocarbon; propanal, aldehyde; propanone, ketone; propanol, alcohol

b. Hydrogen bonds are stronger than polar-polar interactions, which are stronger than dispersion forces. Thus, the alcohol has the highest boiling point, and the hydrocarbon has the lowest boiling point. The aldehyde and the ketone have similar boiling points because they experience the same types of interactions.

FIGURE 23.10 methyl group (CH_3)

Explain

USE VISUALS Have students study the photograph in Figure 23.11. Explain that carboxylic acids are found in many natural products. Ask students to name the acid in the lemons and limes shown. Write the structural formula for the acid on the board. Point out the carboxyl functional groups. Have students name other examples of food products that contain acids and describe the tastes and odors associated with carboxylic acids.

Oxidation-Reduction Reactions

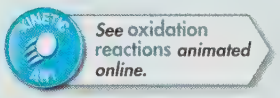
APPLY CONCEPTS Go through the sequence of oxidations that occurs for alkanes. Explain that carbon dioxide is the most oxidized form of carbon, and an alkane is the most reduced form of carbon. Discuss each step as being an example of an oxidation or reduction. Remind students that the loss of hydrogen is oxidation, and the gain of hydrogen is reduction. In any series of oxidations or reductions involving hydrocarbons, an alkane is the least oxidized and an alkyne is most oxidized.

Figure 23.11 Citric Acid
A common carboxylic acid is citric acid, which is found in lemons and limes.
Use Models *How many carboxyl groups does a citric acid molecule have?*

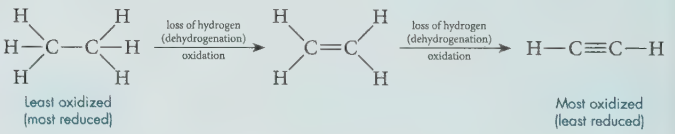
Carboxylic acids are abundant and widely distributed in nature. The lemons and limes in Figure 23.11 contain citric acid, a carboxylic acid that gives citrus fruits their sour flavor. The IUPAC name for citric acid is 2-hydroxypropane-1,2,3-tricarboxylic acid. Many carboxylic acids have common names derived from a Greek or Latin word that describes their natural sources. For example, the common name for ethanoic acid is acetic acid, which comes from the Latin word *acetum*, meaning vinegar. Common household vinegar contains about 5% (v/v) acetic acid. Many carboxylic acids were first isolated from fats and are called **fatty acids.** Propionic acid, the three-carbon acid, literally means first fatty acid.

Like alcohols, carboxylic acids form intermolecular hydrogen bonds. Thus, carboxylic acids have higher boiling and melting points than other compounds of similar molar mass. The low-molar-mass members of the aliphatic carboxylic acid series are colorless, volatile liquids. The higher members of the series are nonvolatile, waxy solids with low melting points. All aromatic carboxylic acids are solids at room temperature.

The carboxyl group in carboxylic acids is polar and readily forms hydrogen bonds with water molecules. As a result, methanoic, ethanoic, propanoic, and butanoic acids are completely soluble in water. After four carbons, however, the solubility drops sharply. Most carboxylic acids are also soluble in organic solvents such as ethanol or propanone.



Oxidation-Reduction Reactions

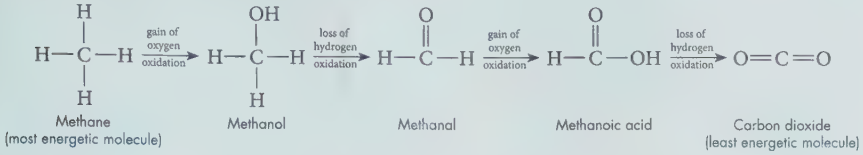


Why is dehydrogenation classified as an oxidation reaction?

The classes of organic compounds you have just studied—aldehydes, ketones, and carboxylic acids—are related by oxidation and reduction reactions. Recall from Chapter 20 that oxidation is the gain of oxygen, loss of hydrogen, or loss of electrons and reduction is the loss of oxygen, gain of hydrogen, or gain of electrons. Also remember that one does not occur without the other.

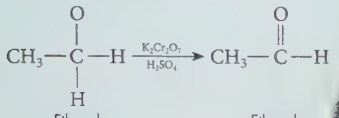
In organic chemistry, the number of oxygen atoms and hydrogen atoms attached to carbon indicates the degree of oxidation of a compound. The fewer hydrogens on a carbon–carbon bond, the more oxidized the bond. Thus, a triple bond is more oxidized than a double bond, which is more oxidized than a single bond.

The loss of a molecule of hydrogen from an organic molecule is called a **dehydrogenation reaction.** It is the opposite of a hydrogenation reaction. Strong heating and a catalyst are usually needed to make dehydrogenation reactions occur. **Dehydrogenation is an oxidation reaction because the loss of each molecule of hydrogen involves the loss of two electrons from the organic molecule.** The remaining carbon electrons pair to make a second or third bond, as shown in the reactions below.



Differentiated Instruction

L1 STRUGGLING STUDENTS Students may find it difficult to understand that oxidation and reduction can be defined in terms of the loss or gain of hydrogen. Pair up students who are having trouble with this concept. Have students write out each series of oxidation-reduction reactions on this and the next few pages of the text, noting the number of hydrogen and oxygen atoms attached to carbon at each step.



L3 ADVANCED STUDENTS Have students assign oxidation numbers to carbon for each step in the sequence of oxidation reactions shown in the text in which methane is converted to carbon dioxide. **Ask** How many molecules of hydrogen are given up by methane? *(2)* How many electrons are lost? *(4)* How many molecules of H_2 would ethane yield? *(3)*

Oxidation in organic chemistry also involves the number and degree of oxidation of oxygen atoms attached to a carbon atom. For example, methane, a saturated hydrocarbon, can be oxidized in steps to carbon dioxide. This occurs if it alternately gains oxygen atoms and loses hydrogen atoms. Methane is oxidized to methanol, then to methanal, then to methanoic acid, and finally to carbon dioxide. The carbon dioxide is most oxidized or least reduced, and methane is least oxidized or most reduced.

The more reduced a carbon compound is, the more energy it can release upon its complete oxidation to carbon dioxide. The oxidation of organic compounds is exothermic. The energy-releasing properties of oxidation reactions are extremely important for the production of energy in living systems. To play a sport, such as the one shown in Figure 23.12, your body must produce energy by oxidation reactions.

Primary alcohols can be oxidized to aldehydes, and secondary alcohols can be oxidized to ketones by warming them with acidified potassium dichromate ($K_2Cr_2O_7$). Tertiary alcohols, however, cannot be oxidized because there is no hydrogen atom present on the carbon atom attached to the hydroxy group. Examples of oxidation of a primary and secondary alcohol are shown below.

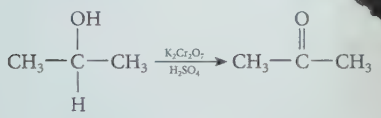


Figure 23.12
Oxidation in Living Systems
Oxidation reactions occur in many daily activities. These athletes are energized by oxidation reactions taking place within the cells of their bodies.

Explore

Teacher Demo

PURPOSE Students observe the oxidation of primary and secondary alcohols to carboxylic acids and ketones, respectively, by chromic acid.

MATERIALS CrO_3, concentrated sulfuric acid, water, 3 test tubes, acetone, ethanol, isopropanol, and *t*-butyl alcohol

PROCEDURE Explain how the loss of a molecule of hydrogen by an alcohol can lead to the formation of a carbonyl group. Prepare an acidic solution of CrO_3 by dissolving 0.25 g CrO_3 in 0.75 mL water and adding 0.25 mL concentrated sulfuric acid. A clear orange solution should be obtained. Set up three test tubes, each containing 1 mL acetone. Dissolve about 5 drops of ethanol, isopropanol, and *t*-butyl alcohol in separate tubes. Add 1–2 drops of chromic acid reagent to each tube and gently tap the tubes to mix. Note any changes that occur. A positive test for a primary or secondary alcohol is indicated by a change in color of the solution from orange to blue-green. No change should occur in the case of *t*-butyl alcohol. Have students record their observations and write the chemical equations for any reactions they observed. **Ask** Why was no reaction observed for the test tube containing t-butyl alcohol? *(There is no hydrogen on the carbon bearing the hydroxy group.)*

UbD Check for Understanding

The Essential Question **What effect does a functional group have on an organic compound?**

Ask When a carbonyl group is attached to a hydroxy group, what is its effect on the organic compound? *(Sample answers: It is a weak acid and has higher boiling and melting points than other compounds of similar molar mass.)*

ADJUST INSTRUCTION If students are having difficulty answering, have them review the text before and after Table 23.7. Then allow them to revise their answers.

Answers

QuickLab

OBJECTIVE After completing this activity, students will be able to describe a positive test for an aldehyde.

TEACHING TIP It may be necessary to warm the test tube in a bath of warm water. *Note*: The silver nitrate solution in the *Materials* list is 5% (w/v).

PREP TIME 20 minutes

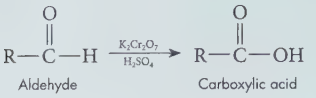
CLASS TIME 30 minutes

SAFETY Do not store Tollens' reagent for extended periods of time. It decomposes on standing and yields an explosive mixture. Avoid skin contact with these chemicals.

EXPECTED OUTCOME The deposition of a silver mirror on the inner walls of the test tube is a positive indicator for the presence of an aldehyde functional group. (The silver mirror can be removed from the inside of the test tube with nitric acid.)

ANALYZE AND CONCLUDE

1. A layer of reflective silver metal is deposited on the inner walls of test tube 1. No reaction is observed in test tubes 2 or 3.
2. In an alkaline solution of silver nitrate, the aldehyde is oxidized to a carboxylic acid according to the following reaction:



$$RCHO(aq) + 2Ag(NH_3)_2OH(aq) \rightarrow 2Ag(s) + RCOO^-(aq) + NH_4^+(aq) + H_2O(l) + 3NH_3(aq)$$

3. The test is useful for distinguishing aldehydes from alcohols and ketones.

Figure 23.13 Fehling's Test
When an aldehyde is mixed with Fehling's reagent (left test tube) and heated, the blue copper(II) ions in Fehling's reagent are reduced to form Cu_2O, a red precipitate (right test tube). Infer ***What is the oxidation state of copper in the product?***

Aldehydes are so easily oxidized that it is difficult to prevent further oxidation to carboxylic acids as shown in the reaction below.

Further oxidation is avoided by removing them from the reaction mixture as they are formed. Unlike aldehydes, ketones are relatively resistant to further oxidation, so there is no need to remove them from the mixture during the reaction.

Tests for aldehydes make use of the ease with which these compounds are oxidized. Benedict's and Fehling's reagents are deep-blue alkaline solutions of copper(II) sulfate. Figure 23.13 illustrates Fehling's test for an aldehyde. When an aldehyde is oxidized with Benedict's or Fehling's reagent, a red precipitate of copper(I) oxide (Cu_2O) is formed. The aldehyde is oxidized to its acid, and copper(II) ions (Cu^{2+}) are reduced to copper(I) ions (Cu^+).

QuickLab

Testing for an Aldehyde

Purpose To distinguish an aldehyde from an alcohol or a ketone using Tollens' reagent

Materials
- 1*M* sodium hydroxide
- 5% silver nitrate
- 6*M* aqueous ammonia
- 4 small test tubes
- test tube rack
- plastic droppers
- glucose solution
- propanone
- ethanol

Procedure

1. Add 1 drop of 1*M* sodium hydroxide to 2 mL of 5% silver nitrate in a test tube. Add 6*M* aqueous ammonia drop by drop, gently agitating the tube after each addition until the brownish precipitate dissolves. This will be your Tollens' reagent.
2. Place 10 drops of Tollens' reagent in each of three clean, labeled test tubes.
3. To test tube 1, add 2 drops of glucose solution. To test tube 2, add 2 drops of propanone. To test tube 3, add 2 drops of ethanol. Gently agitate each test tube to mix the contents.
4. Observe the contents of the test tubes, leaving them undisturbed for at least 5 minutes.

Analyze and Conclude

1. Observe What evidence of a chemical reaction did you observe in test tube 1? In test tube 2? In test tube 3?
2. Describe Write the equation for any chemical reaction you observed.
3. Infer If you observed a chemical reaction in one or more of the test tubes, what practical uses might the reaction have?

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the lab. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Restate the procedures in simpler terms. Allow students to answer in short written phrases or orally.

INTERMEDIATE: LOW/HIGH Draw a picture of the reaction observed in each of the test tubes.

ADVANCED: LOW/HIGH Discuss and help the group write the equations for each of the chemical reactions observed.

818 Chapter 23 • Lesson 3

Esters

What is the general formula of an ester?

Esters are probably the most pleasant and delicious organic compounds one can study. Many esters have pleasant, fruity odors. Esters give blueberries, pineapples, apples, pears, bananas, and many other fruits their characteristic aromas. They also give many perfumes their fragrances. An **ester** is an organic compound in which the —OH of the carboxyl group has been replaced by an —OR from an alcohol. Esters contain a carbonyl group and an ether link to the carbonyl carbon. **The general formula of an ester is RCOOR.**

CHEMISTRY & YOU

Q: *The smell of strawberries is largely due to benzyl acetate. The smell of almonds is largely due to benzaldehyde. How are the general formulas of these compounds similar? How are they different?*

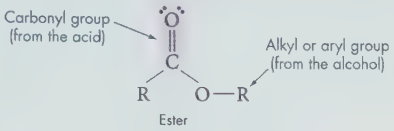


Figure 23.14 shows the esters that contribute to the characteristic odors of bananas and strawberries. Simple esters are neutral substances. Although the molecules are polar, they cannot form hydrogen bonds with one another because they do not contain hydrogen attached to oxygen or another electronegative atom. As a result, only weak attractions hold ester molecules to one another. As you might expect, esters have much lower boiling points than carboxylic acids. The low-molar-mass esters are somewhat soluble in water, but esters containing more than four or five carbons have very limited solubility.

Esters may be prepared from a carboxylic acid and an alcohol. The process is called esterification. The reactants, usually a carboxylic acid and a primary or secondary alcohol, are heated with an acid as a catalyst. The synthesis of ethyl ethanoate from ethanoic acid and ethanol is an example of esterification.

$$\underset{\text{Ethanoic acid}}{CH_3{-}\overset{\overset{O}{\|}}{C}{-}OH} + \underset{\text{Ethanol}}{CH_3CH_2O{-}H} \overset{H^+}{\rightleftharpoons} \underset{\text{Ethyl ethanoate}}{CH_3{-}\overset{\overset{O}{\|}}{C}{-}OCH_2CH_3} + H_2O$$

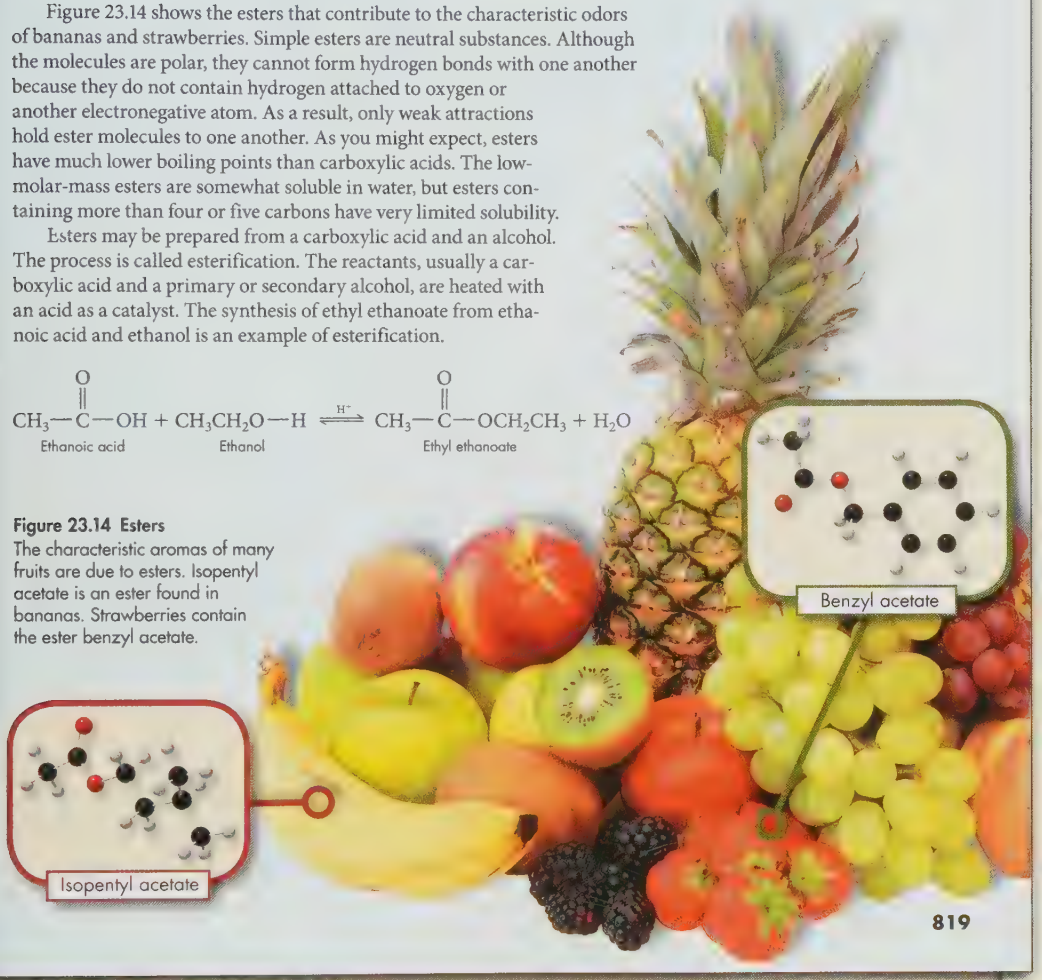

Figure 23.14 Esters
The characteristic aromas of many fruits are due to esters. Isopentyl acetate is an ester found in bananas. Strawberries contain the ester benzyl acetate.

Explore

CHEMISTRY & YOU Both compounds have a carbonyl group and a phenyl group. Benzyl acetate is a 9-carbon ester, and benzaldehyde is a 7-carbon aldehyde.

Teacher Demo

PURPOSE Students will observe the synthesis of an ester from an acid and an alcohol.

MATERIALS water bath, hot plate, test tubes, several carboxylic acids, several corresponding alcohols, concentrated sulfuric acid, filter paper, watch glass

SAFETY AND DISPOSAL Sulfuric acid is caustic and can burn skin and clothing. Neutralize the combined reaction mixtures and flush them down the drain.

PROCEDURE Explain that esters are derivatives of carboxylic acids in which the —OH group of the carboxyl group has been replaced by an —OR group from an alcohol. The synthesis of an ester from an acid and an alcohol is called esterification. Synthesize a variety of fragrant esters in class and give students a chance to smell the products. Set up a water bath on a hot plate to maintain the temperature at about 80°C. To synthesize the ester, mix 1–2 mL (or 0.2–0.6 g if the acid is a solid) of each carboxylic acid with 3–5 mL of the corresponding alcohol in a test tube. Add 1–2 drops of concentrated sulfuric acid and heat for 15 minutes in the water bath. Dip a piece of filter paper into the test tube, and place it on a clean watch glass. Have students record the esters you prepare and their associated odors. Ask them to write the chemical equation for each reaction. Point out that the only difference in these reactions is in the R groups attached to the carboxyl and alcohol functional groups.

EXPECTED OUTCOME

Acid	Alcohol	Odor of Ester
ethanoic	ethyl	apple
ethanoic	isopentyl	banana
ethanoic	pentyl	apricot
ethanoic	octyl	orange
butyric	ethyl	pineapple
salicylic	methyl	wintergreen

Professional Development Note

Scientists Growing Flavors

Scientists are learning how to produce flavor molecules and other naturally occurring compounds in plant cell cultures and genetically altered yeast cells. For example, Japanese scientists are using a tissue culture technique called root culture to produce ginseng for teas and medicines and for a red pigment used in cosmetics.

In the United States, scientists are obtaining vanilla flavor from cells surgically removed from a vanilla orchid and cultured in a glass bioreactor. Prior to any commercial production, a patent application is usually filed, and manufacturers must seek approval from the Food and Drug Administration to use the prepared flavor molecules in food products.

Answers

FIGURE 23.13 +1

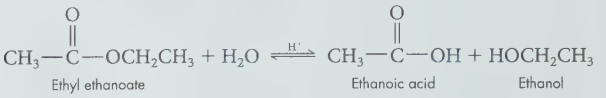
Explain

Esters

START A CONVERSATION Explain that the formation of an ester from a carboxylic acid and an alcohol is an excellent example of dynamic equilibrium. Under the proper conditions, the equilibrium can be shifted greatly in favor of the products. Other conditions favor the decomposition of the ester into the carboxylic acid and alcohol. Have students review Le Châtelier's principle and use it to predict conditions that would favor the reactants and conditions that would favor the products. **Ask** How can a chemist improve the yield of an ester from an esterification reaction? *(Use an excess of a reactant, or remove the water or ester by distillation as it is formed.)*

APPLY CONCEPTS Discuss the base-promoted hydrolysis of an ester. Write a number of examples of reactions on the chalkboard or overhead projector. Explain which part of the ester yields the alcohol and which part yields carboxylic acid products. Ask students about the difference in volatility of the products and how a chemist might separate them once they are formed. Write the molecular structure for propyl ethanoate on the board. **Ask** What products would be formed from the base-promoted hydrolysis of propyl ethanoate? *(propanol and ethanoic acid)*

Evaluate

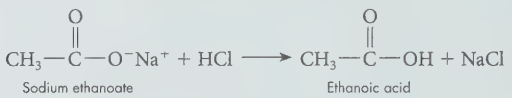


Informal Assessment

Write the molecular structures of vanillin, 3-heptanone, ethyl butanoate, and pentanoic acid on the board. Have students classify each compound as an aldehyde, ketone, ester, or carboxylic acid. Then have students complete the 23.3 Lesson Check.

Reteach

Review the oxidation states of carbon in organic compounds. Remind students that the oxidation state of carbon can cycle from –4 to +4.



If an ester is heated with water for several hours, usually very little happens. In strong acid or base solutions, however, the ester breaks down. An ester is hydrolyzed by the addition of water to produce a carboxylic acid and an alcohol. The reaction is rapid in acidic solution.

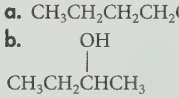
Hydroxide ions also promote this reaction. Usually aqueous solutions of sodium hydroxide or potassium hydroxide are the source of hydroxide ions. Because many esters do not dissolve in water, a solvent such as ethanol is added to make the solution homogeneous. The reaction mixture is usually heated. All of the ester is converted to products. The carboxylic acid product is in solution as its sodium or potassium salt as shown in the example below.

If the reaction mixture is acidified, the carboxylic acid forms.

23.3 Lesson Check

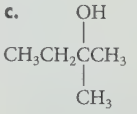
16. Review Describe the structure of the carbonyl groups that are characteristic of aldehydes and ketones.

17. Identify What is the general formula of a carboxylic acid?



18. Explain Why is dehydrogenation an oxidation reaction?

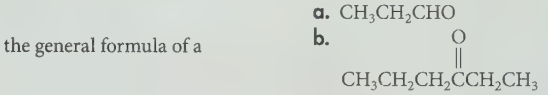
19. Describe What is the general formula of an ester?



20. Predict What products are expected when the following compounds are oxidized?

a. $CH_3CH_2CH_2CH_2OH$

b.



c.

21. Classify Write the IUPAC name for each of the following compounds:

a. CH_3CH_2CHO

b.

c. $CH_3CH_2CH_2CH_2COOH$

22. Describe Draw structural formulas for the following organic compounds:

a. hexanoic acid

b. butanal

c. 2-pentanone

BIG IDEA CARBON CHEMISTRY

23. How can you describe the degree of oxidation of an organic compound?

Lesson Check Answers

16. A carbonyl group is a carbon atom double bonded to an oxygen atom. aldehyde: carbon of the carbonyl group is always joined to at least one hydrogen (RCHO); ketone: carbon is joined to two other carbons (RCOR)

17. RCOOH or RCO_2H

18. The loss of hydrogen (H_2) also results in the loss of two electrons.

19. RCOOR or RCO_2R

20. a. butanal
b. 2-butanone
c. no reaction

21. a. propanal **b.** 3-hexanone
c. pentanoic acid

22. a. $CH_3CH_2CH_2CH_2CH_2COOH$
b. $CH_3CH_2CH_2CHO$
c. $CH_3COCH_2CH_2CH_3$

23. BIG IDEA The fewer hydrogen atoms and the more oxygen atoms a compound has, the more oxidized it is.

Scratch and Sniff Stickers

When you were a kid, you may have been rewarded with a scratch and sniff sticker for an A+ assignment. Many scratch and sniff stickers smell like fruits such as cherries, strawberries, or grapes. Others smell like root beer, pickles, pizza, or even stinky sneakers. Have you ever wondered where the scents come from?

Esters are usually the smelly component used in scratch and sniff sticker technology. The esters used in the stickers are volatile liquids, which explains why you are able to smell them. A single ester or a mixture of esters with the desired odor is contained in numerous tiny brittle capsules that are glued onto the surface of the sticker paper. The capsules are so small that you can barely notice the rough texture of the sticker. When you scratch the sticker, you break some of the capsules and allow the ester molecules to make their way to your nose.

SCRATCH IT When your finger exerts sufficient pressure on the capsules, they rupture.

SNIFF IT The volatile ester molecules that are contained in the capsules are released from each ruptured capsule.

Take It Further

1. **Explain** Why does the smell get more faint as the sticker is continually scratched?
2. **Describe** Methyl butanoate can be used to impart a pineapple aroma. Write a condensed structural formula for this ester.
3. **Infer** Which carboxylic acid and alcohol would you use to prepare ethyl heptanoate, the ester that smells like grapes?

Differentiated Instruction

L1 STRUGGLING STUDENTS Have students write down their favorite scent and then research the IUPAC chemical name and the chemical structure. Then, assign them another scent based on their grasp of the concepts; an easier one for those struggling to gain confidence, and a more difficult one for others.

LPR LESS PROFICIENT READERS Have students handle oranges, lemons, or limes. Draw their attention to the oily residue that may linger on their skin and the aroma left from handling the fruit. For each type of fruit, have the IUPAC chemical name and chemical model available for them to visually associate with the scent.

L3 ADVANCED STUDENTS Have students research the chemical compounds in a favorite perfume or cologne. Challenge students to write the structural formulas for the compounds contained in the product.

CHEMISTRY & YOU

Volatility is a property shared by many organic substances. Volatile substances can vaporize at a rather low temperature, a characteristic that is desirable in the scent chemicals utilized in scratch and sniff applications. It is this characteristic that allows the human nose to detect the chemicals associated with various odors and fragrances as the airborne molecules interact with odorant receptors on olfactory cells in the nasal cavity. These cells send nerve impulses to the olfactory bulb of the brain, which interprets the impulses and identifies the scents. Although the exact mechanisms by which humans and other animals identify and create a memory bank of scents is not yet known, researchers do know that humans can recognize about 10,000 different scents. This is quite a feat, considering that most natural scents are the result of a mixture of chemicals, rather than a single chemical.

Some microencapsulation systems rely on protein polymers to form the capsules. *Challenge students to create their own complex scratch and sniff spots using unflavored gelatin and a variety of scents.* You may need to assist students in the following ways:

- Unflavored gelatin must be softened in cold water before being dissolved in hot water.
- The paper used must be soaked with the gelatin and allowed to dry before testing.

Have students exchange their spots and try to identify the scents used.

Extend

Connecting to PSYCHOLOGY

Psychologists use scents of pleasant things in the form of essential oils. The use of different scents has been used to aid in altering the physiological and mental state of humans and assist in the healing process of physical ailments. Pleasant aromas have been shown to alter moods. The use of this phenomenon is called "aromatherapy" and drives the industry of scented candles and other air fresheners or deodorizers. Some scents have been associated with a more energetic feeling, while others are promoted to provide a calm or relaxed feeling. Provide a selection of aromatherapy oils and ask students to explain the effect each has on their mood. Be aware, however, that some scents may trigger allergic reactions or severe headaches in some individuals. Ask students to identify any scents that might have this effect before beginning the activity.

Answers

TAKE IT FURTHER

1. More capsules are broken and depleted of the ester molecules within the capsules.
2. $CH_3CH_2CH_2COOCH_3$
3. heptanoic acid and ethanol

LESSON 23.4

Key Objectives

23.4.1 DESCRIBE how addition polymers are formed.

23.4.2 DESCRIBE how condensation polymers are formed.

Additional Resources

- Reading and Study Workbook, Lesson 23.4
- Probeware Laboratory Manual

PearsonChem.com

Engage

CHEMISTRY & YOU Relate the construction of a skydiver chain to the formation of a polymer. **Ask** What is the repeating unit, or monomer, in the chain? *(each person of the chain)* **Ask** What do you think are some of the characteristics of monomers? *(Answers will vary. Students may suggest that monomers must have the ability to be joined together, must be small molecules, or must be chemically reactive.)*

Build Background

Show students pictures of a disposable baby diaper, nylon stockings, and PVC pipe. Explain that each of the items are everyday items made of polymers.

Foundations for Reading

BUILD VOCABULARY The word *polymer* comes from the Greek word *poly*, meaning "many," and the Greek word *meros*, meaning "parts." A polymer is a compound that is formed by the covalent bonding of repeating small parts, called monomers.

23.4 Polymers

CHEMISTRY & YOU

Q: *How do organic molecules bond together to form long chains?* Similar to the way these skydivers are linked together in a chain, organic molecules can bond together to form long molecular chains. As more molecules bond together, the molecular chains grow longer and longer.

Key Questions

- *How does an addition polymer form?*
- *How are condensation polymers formed?*

Vocabulary

- polymer
- monomer

Addition Polymers

How does an addition polymer form?

Most of the reactions that you have learned about so far involve reactants and products of low molar mass. Some of the most important organic compounds that exist, however, are giant molecules called polymers. Each day, you see many different polymers. For example, the materials you know as plastics are polymers. The kinds and uses of plastics are numerous indeed!

A **polymer** is a large molecule formed by the covalent bonding of repeating smaller molecules. The smaller molecules that combine to form a polymer are called **monomers.** Some polymers contain only one type of monomer. Others contain two or more types of monomers. The reaction that joins monomers to form a polymer is called polymerization. Most polymerization reactions require a catalyst.

An addition polymer forms when unsaturated monomers react to form a polymer. Ethene undergoes addition polymerization. The ethene molecules bond to one another to form the long-chain polymer polyethylene as described in the equation below.

$$x\mathrm{CH_2{=}CH_2} \longrightarrow \mathrm{H{+}CH_2{-}CH_2{+}_xH}$$

Ethene (ethylene) → Polyethylene

Note that the letter x on the reactant side of the equation refers to the number of monomers (in this case, ethene) that combine to form the polymer. The x on the product side indicates the number of repeating units in the polymer. Parentheses are used to identify the repeating unit (in this case, $-\mathrm{CH_2}-\mathrm{CH_2}-$).

Polyethylene, which is chemically resistant and easy to clean, is an important industrial product. It is used to make plastic bottles, containers, and even toys, such as the one in Figure 23.15.

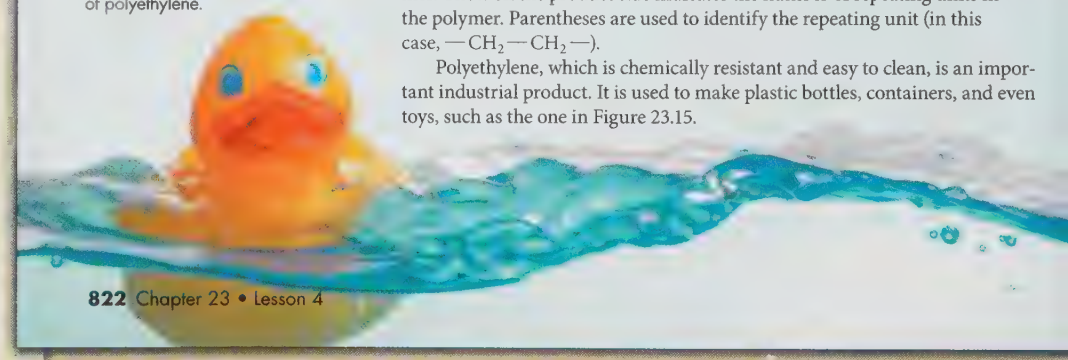


Figure 23.15 Polyethylene Many familiar household items, including this unsinkable duck, are made of polyethylene.

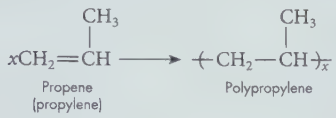
Focus on ELL

1 CONTENT AND LANGUAGE Have students identify the prefix for each vocabulary term. Ask students to list other words that use the same prefixes *(Sample answers: polyatomic, polygon, monoatomic, monorail)*. Ask students to predict the meaning of the key vocabulary using the list generated.

2 FRONTLOAD THE LESSON Create two chains of pop beads: one made from a solid color of beads and one of mixed colors. Explain that the two chains represent polymers. Ask students to study each chain and identify their similarities and differences. Ask students to predict what each chain has in common with polymers.



3 COMPREHENSIBLE INPUT Write the product of the first addition polymer on the board, and beside it, write the condensed structural formula for butane. Erase the parentheses and parenthetical subscripts for each, and write them in a contrasting color. Use the two formulas to demonstrate how the parentheses and their accompanying subscript indicate the presence of multiple identical units within each molecule.

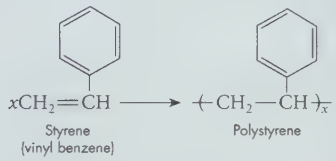


Figure 23.16 Polymer Products
a. Polypropylene is used in the manufacture of a variety of items that require stiffness, including these kazoos.
b. Polystyrene foam is used to make protective helmets.
Infer ***How does the polystyrene foam in a helmet protect a cyclist during an accident?***

The physical properties of polyethylene can be controlled by shortening or lengthening the carbon chains. Polyethylene that contains relatively short chains ($x = 100$) has the consistency of paraffin wax. Polyethylene with long chains ($x = 1000$) is harder and more rigid.

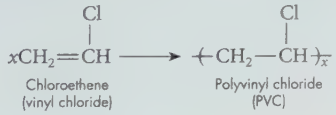

Figure 23.16 shows some items made from polymers of substituted ethenes. Polypropylene, a stiffer polymer than polyethylene, is used extensively in utensils and beverage containers. Polypropylene is prepared by the polymerization of propene.

Polystyrene, in the form of a rigid foam, is a poor heat conductor. This makes it useful for insulating homes and for manufacturing molded items such as coffee cups and picnic coolers. Polystyrene is prepared by the polymerization of styrene as shown in the reaction below.

Many halocarbon polymers, including polyvinyl chloride (PVC), have useful properties. For example, polyvinyl chloride is used to make plumbing pipes, rainwear, and garden hoses. It is also produced in sheets, sometimes with a fabric backing, for use as a tough plastic upholstery covering. Vinyl chloride is the monomer of polyvinyl chloride.

READING STRATEGY Students may have trouble understanding the concept of a polymer as an array of repeating units. Drawing a segment containing 3 or 4 monomers of each polymer will help students visualize the polymer.

Explain

Addition Polymers

START A CONVERSATION Discuss the similarities between the addition of hydrogen and halogens to alkenes and the formation of addition polymers. Explain that chemists have also found that when certain catalysts are used, alkenes will add to one another to form a long chain of hydrocarbon units. **Ask** What is a catalyst? *(A catalyst is a substance that increases the rate of a reaction without being used up in the reaction.)*

USE MODELS Write the formula for the simplest repeating unit of a polymer on the board. Ask students to identify the polymer and to write out the structure for the polymer showing how three successive monomers are linked together. **Ask** Why can't we write an exact formula for a polymer? *(The length of the carbon chain varies from polymer molecule to polymer molecule. The best that can be done is to write the formula for the simplest repeating unit, the monomer, in parentheses. The subscript x indicates a very large number.)*

Extend

Connect to MATHEMATICS

Have students write a paragraph comparing and contrasting the chemistry concept of polymers and monomers to the mathematical concept of polynomials and monomials. Encourage students to use diagrams as well as words to describe their analogy.

Professional Development Note

The First Plastic—Celluloid

One of the first plastics, developed by an Englishman named Alexander Parkes, was a synthetic ivory named pyroxlin. Parkes marketed it under the trade name "Parkesine," and it won a bronze medal at the 1862 World's Fair in London. Parkesine was made from cellulose treated with nitric acid and a solvent. An American amateur inventor named John Wesley Hyatt later improved the product. Because cellulose was the main constituent used in the synthesis of his new material, Hyatt named it celluloid. A large variety of objects were made of celluloid, and it was a huge success. However, celluloid had a dangerous defect—it burned easily and tended to explode. Hyatt liked to tell stories about celluloid billiard balls exploding when struck very hard. Today, celluloid is used only to make table-tennis balls.

Answers

FIGURE 23.16 It absorbs a large portion of the force of impact (the energy is used to deform the foam), leaving only part of the force to be suffered by the head and brain.

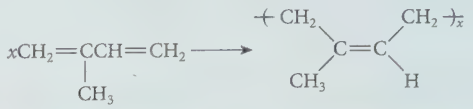
Explore

Teacher Demo

PURPOSE Students will better understand how monomers link together to form polymers.

PROCEDURE Bring a length of metal-link chain to class. Use the metal chain as a model for a polymer. Explain that a polymerization reaction is a reaction that joins monomers to form a polymer. Point out the features in the chain that are similar to a polymer molecule. In addition, model a polymerization reaction using paperclips. Each paperclip represents a monomer. Explain that each end of the paperclip represents a reaction site. Build a chain by successively connecting one paperclip to another. The chain formed is analogous to a polymer. Point out that the main differences between polymers in organic chemistry are due to the type of monomers used to form the chains.

Explain



APPLY CONCEPTS Have students study the chemical equations for the formation of the addition polymers discussed in this section. Write the equations on the board and help students identify the repeating units. Discuss the features of an addition polymerization and how the name of a polymer is derived from the monomer units. Bring to class samples of items that are composed of addition polymers. Have students describe and compare their physical characteristics. **Ask** What are some of the advantages of synthetic polymers over metals and other natural materials? *(They are moldable, lightweight, chemically resistant, and easy to clean.)*

Polytetrafluoroethene (PTFE) is the product of the polymerization of tetrafluoroethene monomers. PTFE is very resistant to heat and chemical corrosion. You are probably familiar with this polymer as a coating on nonstick cookware. PTFE is also used to insulate wires and cables. Because PTFE is very durable and slick, it is formed into bearings and bushings used in chemical reactors. It also is suspended in motor oils as a friction-reducing agent.

$$x\mathrm{CF_2{=}CF_2} \longrightarrow \text{-}(\mathrm{CF_2{-}CF_2})_x\text{-}$$

Tetraflouroethene — PTFE

Polyisoprene is the polymer that constitutes natural rubber. The monomer of polyisoprene, isoprene, is harvested from tropical plants such as the rubber tree. Polyisoprene is used to make rubber bands, soles of athletic shoes, and many other common items. Figure 23.17 shows how isoprene is used in the manufacture of tires.

Isoprene — Polyisoprene

Figure 23.17 Natural Rubber

Rubber is harvested from tropical plants. Harvesters cut the trees, and the sap, which contains isoprene, is collected in a vessel such as a bowl.

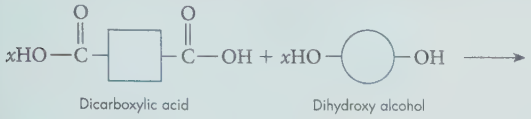
As the harvested rubber dries, the isoprene polymerizes and changes form. For higher-grade rubber, the polymerization occurs under controlled conditions.

Finally, the manufacturer processes and molds the polymer to form the desired product.

Differentiated Instruction

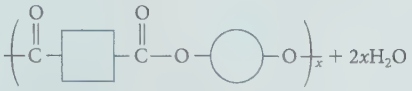
LPR LESS PROFICIENT READERS Have students collect several household items composed of different polymer materials. Ask them to create a table listing the items and the plastic container codes found on the bottom of each item. Have students do research to find out how the codes are involved in recycling.

L1 STRUGGLING STUDENTS Have student pairs create ball-and-stick models for the reactants of each reaction described in the lesson. Have students manipulate the models to form the products of the reactions by removing the appropriate molecules and creating the new bonds.



L3 ADVANCED STUDENTS Have students do research on the pioneering work of Elias James Corey, a Harvard University professor and Nobel Prize-winning organic chemist. Tell students that his work led to the synthesis of more than 100 important drugs and other naturally occurring compounds. Ask students to write a short report on their findings.

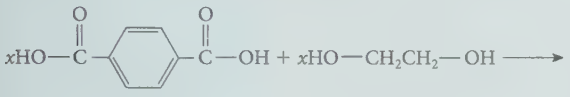
Condensation Polymers



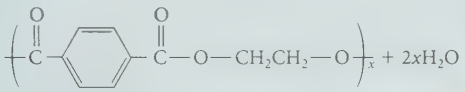
How are condensation polymers formed?

The formation of a polyester is a common example of condensation polymerization. **Condensation polymers are formed by the joining of monomers with the loss of a small molecule such as water.** Polyesters are polymers that consist of many repeating units of dicarboxylic acids and dihydroxy alcohols joined by ester bonds.

The formation of a polyester can be represented by a block diagram, which shows only the functional groups involved in the polymerization reaction. The squares and circles represent unreactive parts of the organic molecules. Condensation polymerization requires that there be two functional groups on each monomer molecule.



Dicarboxylic acid — Dihydroxy alcohol



Representative polymer unit of a polyester

The polyester polyethylene terephthalate (PET) is formed from terephthalic acid and ethylene glycol as shown in the reaction below.

Terephthalic acid — Ethylene glycol

Representative polymer unit of PET

Figure 23.18 shows two very different products made from PET: water bottles and a fleece jacket. But, in fact, the fabric of the jacket is made from recycled PET bottles. PET fibers form when the compound is melted and forced through tiny holes in devices called spinnerettes. The fibers are used for tire cord and permanent-press clothing. PET fibers are often blended with cotton to make clothing that is more comfortable on hot, humid days than those containing 100% polyester. These clothes retain the wrinkle resistance of 100% polyester. Woven PET fiber tubing can be used to replace major blood vessels. PET melts may also be forced through a narrow slit to produce sheets of film that are used extensively on credit cards and as coverings for frozen dinners.

CHEMISTRY & YOU

Q: *Polymers make up most of the bottles, containers, and packaging that you see around you. Try to identify the polymers in some of these items. How would you classify them—as additional polymers or condensation polymers?*

Figure 23.18 Recycling PET Plastic bottles from which you sip your drink may one day be part of someone else's wardrobe. It only takes about a dozen large bottles that are made from PET to make one fleece jacket.

Explain

Condensation Polymers

APPLY CONCEPTS Explain that the key to polymerization is the ability of molecules to form repeating chains. For this to happen, each reacting molecule must have at least two reactive sites. In addition polymerization, the two active sites become available as double bonds are opened up. In condensation polymerization, the sites become available as two groups (such as —H and —OH groups) are split off the molecules.

Extend

Connect to MEDICINE

Have students research the use of synthetic polymers in medicine. Some applications include prosthetics, skin substitutes, artificial artery grafts, and heart valve replacements.

UbD Check for Understanding

The Essential Question **How are chemical reactions used in organic chemistry?**

Assess students' understanding of how addition and condensation reactions are used to create organic polymers by writing the following cloze item on the board and asking them to fill in the blanks:

_____ reactions are used to form polymers from alkenes and alkynes.
_____ reactions are used to form polymers when at least one reactant has a functional group containing –OH. *(addition; condensation)*

ADJUST INSTRUCTION If students are having difficulty distinguishing between the two types of reactions, remind students to think about what happens when condensation forms on a cold surface. *(Water collects on the surface.)* Then, have students review the text associated with the lesson's key questions and answers.

Explore

TeacherDemo

PURPOSE Students observe the synthesis of nylon.

MATERIALS 5% aqueous solution of 1,6-hexanediamine, small beaker, 20% sodium hydroxide, dropper, 5% solution of adipoyl chloride in cyclohexane, forceps or tongs, water, paper towel

SAFETY Wear safety goggles, a chemical-resistant apron, and chemical-resistant gloves while preparing solutions and performing the demonstration.

PROCEDURE Pour 5 mL of a 5% aqueous solution of 1,6-hexanediamine into a small beaker. Add 5 drops of 20% sodium hydroxide. Slowly pour 5 mL of a 5% solution of adipoyl chloride in cyclohexane down the wall of the beaker. A two-phase system will form, and a polymer film will appear at the interface. Use forceps or tongs to slowly draw out a long strand of nylon. Rinse thoroughly with water and set it on a paper towel to dry. Have students examine the color, hardness, and strength. Discuss the uses of nylon, and explain that it is a polyamide and a condensation polymer.

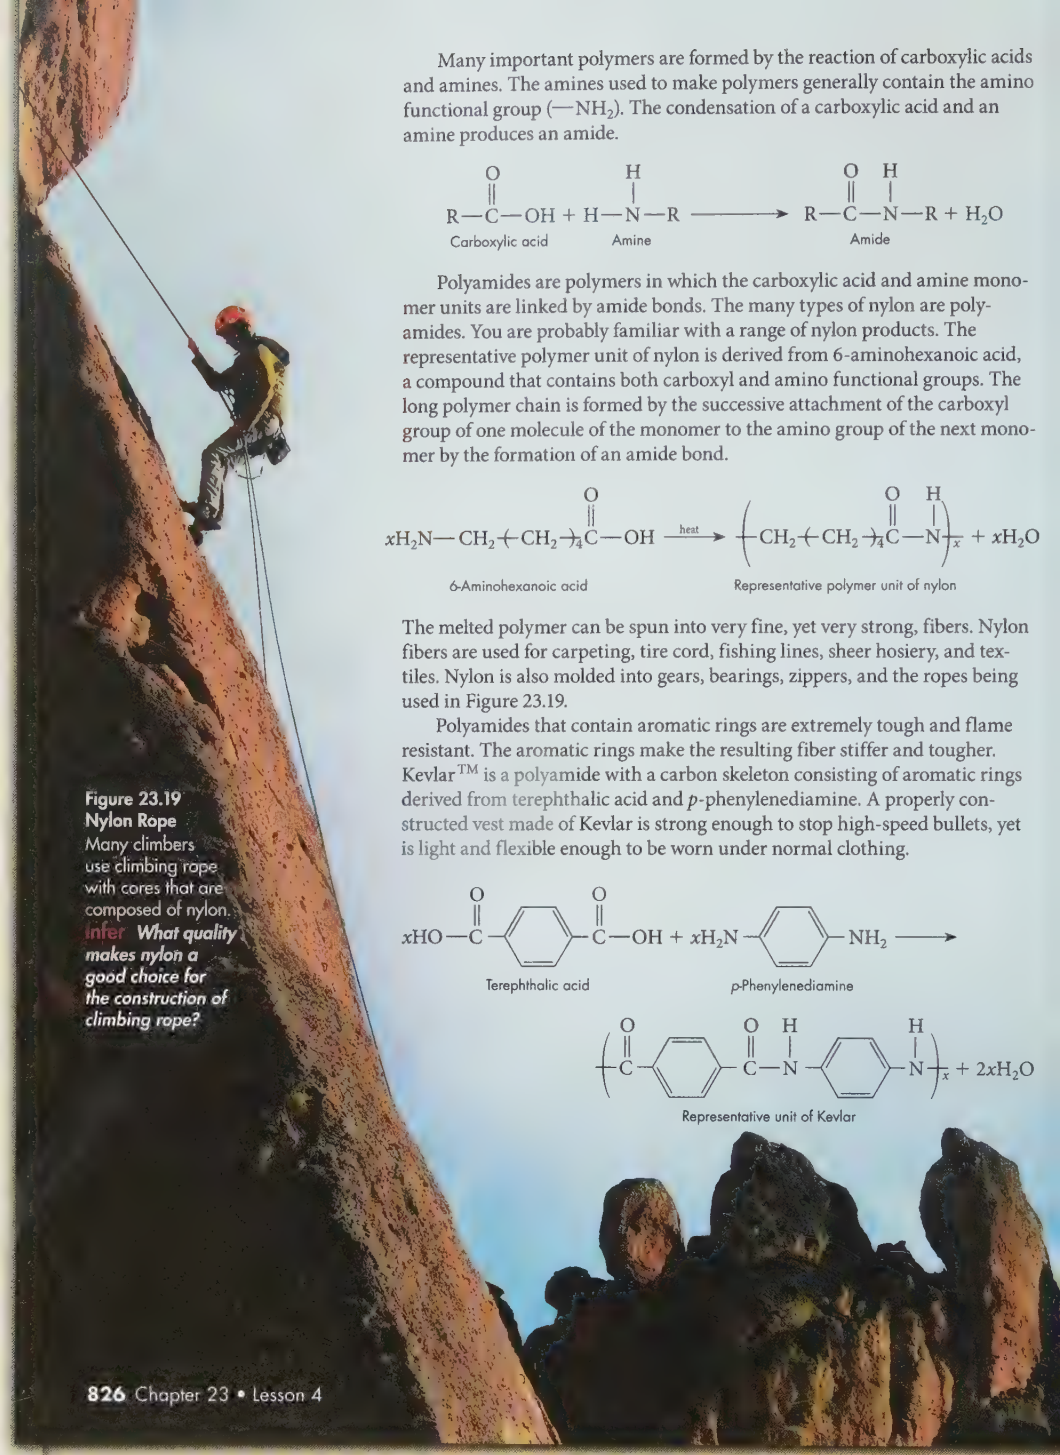


Figure 23.19 Nylon Rope Many climbers use climbing rope with cores that are composed of nylon. **Infer** *What quality makes nylon a good choice for the construction of climbing rope?*

Many important polymers are formed by the reaction of carboxylic acids and amines. The amines used to make polymers generally contain the amino functional group ($-NH_2$). The condensation of a carboxylic acid and an amine produces an amide.

Polyamides are polymers in which the carboxylic acid and amine monomer units are linked by amide bonds. The many types of nylon are polyamides. You are probably familiar with a range of nylon products. The representative polymer unit of nylon is derived from 6-aminohexanoic acid, a compound that contains both carboxyl and amino functional groups. The long polymer chain is formed by the successive attachment of the carboxyl group of one molecule of the monomer to the amino group of the next monomer by the formation of an amide bond.

The melted polymer can be spun into very fine, yet very strong, fibers. Nylon fibers are used for carpeting, tire cord, fishing lines, sheer hosiery, and textiles. Nylon is also molded into gears, bearings, zippers, and the ropes being used in Figure 23.19.

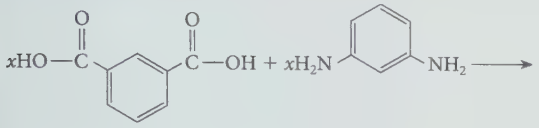
Polyamides that contain aromatic rings are extremely tough and flame resistant. The aromatic rings make the resulting fiber stiffer and tougher. Kevlar™ is a polyamide with a carbon skeleton consisting of aromatic rings derived from terephthalic acid and *p*-phenylenediamine. A properly constructed vest made of Kevlar is strong enough to stop high-speed bullets, yet is light and flexible enough to be worn under normal clothing.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the Small-Scale Lab on page 828. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Model the procedure for the beginning-level student. Give each student a part in the lab.

INTERMEDIATE: LOW/HIGH Rewrite the 3-step procedure into a series of simpler steps.



ADVANCED: LOW/HIGH Have students help students with lower proficiencies with the written answers and predictions.

826 Chapter 23 • Lesson 4

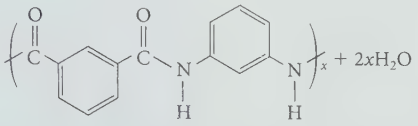


Figure 23.20 Nomex Clothing Flame-resistant clothing is made of Nomex, a polyamide with aromatic rings.

Nomex™ is another polyamide that contains aromatic rings. It is used in the fabrication of flame-resistant building materials and in the manufacture of the flame-resistant clothing the firefighter wears in Figure 23.20. Nomex is a poor conductor of electricity. Because it is also rigid, it is used to make parts for electrical fixtures. Nomex is a polyamide made from isophthalic acid and *m*-phenylenediamine as shown in the reaction below.

Isophthalic acid *m*-Phenylenediamine

Representative unit of Nomex

Proteins, which are polyamides of naturally occurring molecules, rank among the most important of all biological molecules. You will learn about these polymers in more detail in Chapter 24.

23.4 LessonCheck

24. **Review** Describe how addition polymers form.

25. **Review** How do condensation polymers form?

26. **Compare** What is a polymer? A monomer?

27. **Describe** What structure must a monomer have if it is to undergo addition polymerization?

28. **Identify** What is formed when a carboxylic acid and an amine combine? Give an example of the type of polymer that is formed by this reaction.

29. **Explain** How is water involved in the formation of a condensation polymer?

30. **Use Analogies** Write an analogy that you can use to describe to a middle-school student how a polymer is constructed from monomers. Use diagrams as well as words to describe your analogy.

31. **Identify** Give names and uses for three polymers you encounter in your home.

Lesson Check Answers

24. They form when unsaturated monomers react and link to one another.

25. They form by the joining of monomers, usually with loss of water.

26. A polymer is a large molecule formed by the covalent bonding of repeating small molecules. Monomers are the smaller molecules that combine to form the repeating unit of a polymer.

27. an unsaturated carbon-carbon bond

28. an amide bond; Nylon, Kevlar, and Nomex are polyamides.

29. Water is a product of most condensation polymerizations.

30. Students' analogies might include putting together a toddler's plastic pop beads, stringing a bead necklace, or making a paperclip or popcorn chain.

31. Answers will vary.

Extend

Explain that synthetic polymers can be traced to the unique bonding ability of carbon. To show how small changes in the structures of monomers can lead to dramatic differences in physical properties, ask students to compare polymers based on ethene and vinyl chloride.

Evaluate

Informal Assessment

Have students write sentences, in their own words, describing what takes place during the formation of a polymer. **Ask** What is the difference between an addition polymer and a condensation polymer? Give examples of each. *(An addition polymer is formed when unsaturated monomers react to form a polymer. One example is the reaction of ethene to form polyethylene. Condensation polymers are formed by the head-to-tail joining of monomer units. The other product of the condensation reaction is a small molecule such as water.)* Then, have students complete the 23.4 Lesson Check.

Reteach

Remind students that the area of chemistry devoted to the study of polymers involves more than just plastics. Synthetic fibers are used to create clothing, automobile tires, and materials used in the medical and dental fields. Guide students to examine the structures throughout the lesson and then have students describe the uses of some addition and condensation polymers.

Answers

FIGURE 23.19 It can be spun into fibers that are small enough to allow a firm grip with your hands and strong enough to support the weight of your body without breaking.

Small-Scale Lab

OBJECTIVE After completing this activity, students will be able to use a borax solution to cross-link carbohydrate polymers, write structural formulas for cross-linked polymers, and relate the properties of some polymers to their structures.

Students tend to think of polymerization as a large-scale industrial process. This lab shows that polymers can be synthesized on a much smaller scale.

SKILLS FOCUS observing, inferring, drawing conclusions, interpreting diagrams, comparing and contrasting

PREP TIME 30 minutes

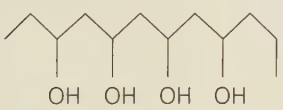
CLASS TIME 30 minutes

MATERIALS 3 1/2-oz plastic cups, soda straw, powdered guar gum, plastic spoons, 4% borax solution, pipet, corn starch or liquid laundry starch, paper, metric ruler, white school glue

ADVANCE PREPARATION Prepare the solution.

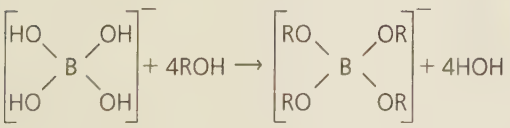
Solution	Preparation
4% borax	10 g $Na_2B_4O_7 \cdot 10H_2O$ in 250 mL

SAFETY AND DISPOSAL Students should not take home the polymers as the mixtures tend to develop mold in a few days. Dispose of these polymers in the waste basket. While the cross–linked polymers are non-toxic, borax is toxic if ingested. Remind students to wash their hands thoroughly when finished.



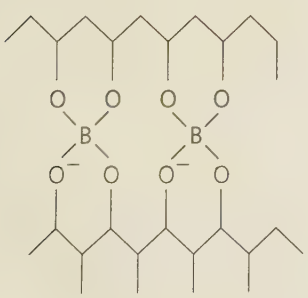
TEACHING TIPS School glue adheres to the stirring spoon as it cross-links. Decant any excess liquid that does not adhere. Wooden craft sticks can be substituted for plastic spoons if desired.

EXPECTED OUTCOME Students will make a polymer that has some liquid properties and some solid properties.



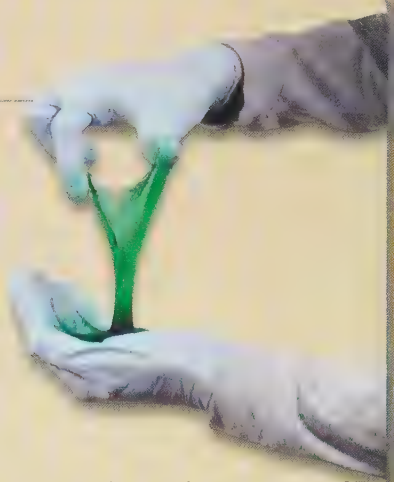
ANALYZE

1. The polymer is a viscous gel that oozes. It has properties of both a liquid and a solid.



2.

3.



4.

Small-Scale Lab

Polymers

Purpose

To cross-link some polymers and examine their properties

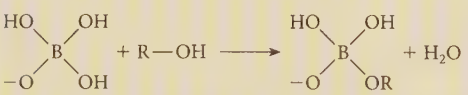
Materials

- 3½-oz plastic cup
- soda straw
- guar gum powder
- plastic spoon
- 4% borax solution
- pipet
- food coloring (optional)

Procedure

1. Half fill a 3½-oz cup with water. Add food coloring to the water if you want the polymer to be colored.

2. Use a soda straw as a measuring scoop to obtain approximately 2 cm of powdered guar gum. **CAUTION** *Do not use your mouth to draw up the guar gum into the straw.* Gently sprinkle the guar gum powder into the water while stirring with a plastic spoon. Add the guar gum powder slowly to prevent it from clumping. Stir the mixture well.



3. While stirring, add one full pipet (about 4 mL) of borax solution. Continue to stir until a change occurs.

Analyze

1. Is the polymer you just made a liquid or a solid? What special characteristics does it have?

2. Guar gum is a carbohydrate, a polymer with many repeating alcohol functional groups (—OH). Draw a zigzag line to represent a crude polymer chain. Add —OH groups along the chain to represent the alcohol functional groups.

3. Borate ions combine with alcohol to form water and borate complexes of the alcohol as shown below. Write a similar equation that replaces all of the —OH groups on the borate with —OR groups.

4. If two polymer chains each contain two nearby —OH groups, borate will cross-link the polymer chains by forming a complex with two alcohols on each chain. Draw a structure similar to the one you drew for Question 3, but replace your four R groups with two polymer chains.

You're the Chemist

1. Design an Experiment! Try using borax to cross-link other common carbohydrate polymers, such as cornstarch or liquid laundry starch. For each polymer, half fill a 3-oz cup with the chosen carbohydrate polymer and add enough water to bring the liquid to within about 1 cm of the rim. Stir carefully and thoroughly. Add one full pipet (about 4 mL) of borax solution while stirring. Describe the similarities and differences between this cross-linked polymer and the polymer you made previously. Compare the properties of these polymers.

2. Analyze Data! Cut a 1 cm × 15 cm strip of paper. Use a drop of glue or a stapler to fasten one end of the paper strip to the other end to form a ring. Now cut out some identical-sized strips of paper, and glue or staple them together into an interlocking chain of paper rings. Explain how this chain is like a polymer. Make another paper ring that cross-links your chain to one of your classmates' chains. Explain how these linked chains are like cross-linked polymers.

YOU'RE THE CHEMIST

1. Through experimentation, students are able to produce a variety of polymers with different properties. Students should compare and contrast the properties of the various polymers they make.
2. The chain is similar to a polymer because it contains many repeating units linked end to end.

FOR ENRICHMENT Have students quantify the synthesis of the polymer by varying the amount of water used in the reaction.

23 Study Guide

BIGIDEAS

CARBON CHEMISTRY AND REACTIONS

Functional groups affect the physical and chemical properties of organic compounds. Chemical reactions can be used to change the structure of organic molecules, often by introducing a new functional group. Substitution, addition, oxidation-reduction, and polymerization reactions are commonly used in organic chemistry.

23.1 Introduction to Functional Groups

- Organic compounds can be classified according to their functional groups.
- The general formula of a halocarbon is RX, where X is a halogen substituent.
- Substitution reactions are an important method of introducing new functional groups to organic molecules.

- functional group (798)
- halocarbon (800)
- alkyl halide (800)
- aryl halide (800)
- substitution reaction (801)

23.2 Alcohols, Ethers, and Amines

- The general formula of an alcohol is ROH.
- Addition reactions are an important method of introducing new functional groups to organic molecules. They are also used to convert alkenes to alkanes.
- The general formula of an ether is ROR.
- The general formula of an amine is RNH_2, R_2NH, or R_3N.

- alcohol (804)
- hydroxy group (804)
- fermentation (807)
- addition reaction (807)
- hydration reaction (808)
- hydrogenation reaction (809)
- ether (810)
- amine (811)

23.3 Carbonyl Compounds

- The C═O functional group is present in aldehydes and ketones.
- The general formula of a carboxylic acid is RCOOH.
- Dehydrogenation is an oxidation reaction because the loss of each molecule of hydrogen involves the loss of two electrons from the organic molecule.
- The general formula of an ester is RCOOR.

- carbonyl group (812)
- aldehyde (812)
- ketone (812)
- carboxyl group (815)
- carboxylic acid (815)
- fatty acid (816)
- dehydrogenation reaction (816)
- ester (819)

23.4 Polymers

- An addition polymer forms when unsaturated monomers react to form a polymer.
- Condensation polymers are formed by the joining of monomers with the loss of a small molecule such as water.

- polymer (822)
- monomer (822)

What's Online

Review and Assessment Resources

Have students practice solving more functional group problems using the Chapter 23 Online Problem Set.

Study Tip

IDENTIFY KEY CONCEPTS AND VOCABULARY For each lesson of the chapter, read the key concepts that are listed in the Study Guide. Then review the chapter text for any concepts that you do not fully understand. Next, define each vocabulary term in your own words and check definitions against the text's definitions. When you check the text, read all the related text, not just the sentence that defines the boldfaced vocabulary term.

Focus on ELL

5 ASSESS UNDERSTANDING Create a formative assessment for each lesson to determine students' level of understanding.

BEGINNING

LOW Create an assessment in which students match a picture or diagram to the corresponding word or concept.

HIGH Create an assessment in which students list characteristics of the different functional groups.

INTERMEDIATE: LOW/HIGH Create a multiple-choice assessment that measures students' understanding of the key concepts.

ADVANCED: LOW/HIGH Create an assessment that involves comparing and contrasting different functional groups.

UbD Performance Tasks

MAKING SUBSTITUTIONS Carboxylic acids react with thionyl chloride ($SOCl_2$) to form acid chlorides, releasing SO_2 and HCl as byproducts. Have students research the IUPAC naming conventions for acid chlorides. Then have them write an equation for the production of an acid chloride from the carboxylic acid of their choice and name the product.

POLYMERIZED Research one of the many items shown in Lesson 23.4. Explain the polymer used to create the item. Describe the structure of the polymer and how the structure helps to make the item usable. Determine whether the item is recyclable or not.

Answers

LESSON 23.1

32. any carbon-containing group

33. **a.** $ClCH_2CCl_2CH_3$ (Cl, Cl) **b.**  **c.** 

34 **a.** 3-chloropropene
b. 1,2-dichloro-4-methylpentane
c. 1,3-dibromobenzene

35. **a.** 

b.

36. **a.**  **b.** 
c. $CH_3CH(OH)CH_3$ **d.** 

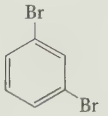
LESSON 23.2

37. **a.** 2-propanol
b. 1,2-propanediol
c. 2-methyl-2-propanol

38. **a.** $CH_2(Br)CH_2$ bromoethane **b.** $CH_2(Cl)CH_2(Cl)$ 1, 2-dichloroethane
c. $CH_2(OH)CH_2$ ethanol **d.** $CH_2(H)CH_2$ ethane
e. $CH_2(Cl)CH_2$ chloroethane

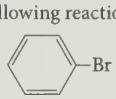
39. **a.** $CH_2(Br)CH(Br)CH_2CH_3$ **b.** $CH_3CH(I)CH(I)CH_3$ **c.** $CH_3CH(H)CH(Br)CH_3$
d. $CH_3CH(H)CH(H)CH_3$ **e.** 

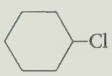
23 Assessment

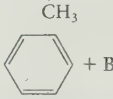


* Solutions appear in Appendix E

Lesson by Lesson







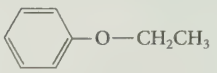
23.1 Introduction to Functional Groups

32. What does R in the formula RCH_2Cl represent?

***33.** Write a structural formula for each compound.
a. 1,2,2-trichlorobutane
b. 1,3,5-tribromobenzene
c. 1,2-dichlorocyclohexane

34. Name the following halocarbons:
a. $CH_2{=}CHCH_2Cl$
b. $CH_3CHCH_2CHCH_2Cl$ (CH_3, Cl)
c. 

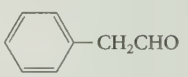
35. Write structural formulas and give IUPAC names for all the isomers of the following compounds:
a. $C_3H_6Cl_2$ **b.** C_4H_9Br



36. What organic products are formed in the following reactions?
a.  $+ NaOH \xrightarrow{heat}$ ____ $+ NaBr$
b.  $+ NaOH \longrightarrow$ ____ $+ NaCl$
c. $CH_3CHCl + NaOH \longrightarrow$ ____ $+ NaCl$ (CH_3)
d.  $+ Br_2 \xrightarrow{catalyst}$ ____ $+ HBr$

23.2 Alcohols, Ethers, and Amines

***37.** Give the IUPAC names for these alcohols.
a. $CH_3CH(OH)CH_3$
b. $CH_2(OH)CH(OH)CH_3$
c. $(CH_3)_3COH$



***38.** Write structures and names of the products obtained upon addition of each of the following reagents to ethene.
a. HBr **b.** Cl_2 **c.** H_2O **d.** H_2 **e.** HCl

39. Write the structure for the expected product from each reaction.
a. $CH_2{=}CHCH_2CH_3 + Br_2 \longrightarrow$
b. $CH_3CH{=}CHCH_3 + I_2 \longrightarrow$
c. $CH_3CH{=}CHCH_3 + HBr \longrightarrow$
d. $CH_3CH{=}CHCH_3 + H_2 \longrightarrow$
e.  $+ Cl_2 \longrightarrow$

40. Give the IUPAC and common names for the following ethers:
a. $CH_3OCH_2CH_3$
b. 
c. $CH_2{=}CHOCH{=}CH_2$
d. $CH_3CHOCHCH_3$ (CH_3, CH_3)

41. Name the following amines:
a. $CH_3CH_2CH_2CH_2NH_2$
b. $CH_3CH_2NH_2$

23.3 Carbonyl Compounds

***42.** Give the IUPAC names for the following carbonyl compounds:
a. CH_3CCH_3 (O) **d.** $CH_3CH_2CCH_2CH_2CH_3$ (O)
b. CH_3CHO **e.** 
c. $CH_3CH(CH_3)CH_2CHO$ **f.** $CH_3(CH_2)_3COOH$

43. Write the structure for the expected organic product from each reaction.
a. $CH_3CH_2OH \xrightarrow{K_2Cr_2O_7,\ H_2SO_4}$
b. $CH_3CHO \xrightarrow{K_2Cr_2O_7,\ H_2SO_4}$
c. $CH_3CH_2CH_2CHO \xrightarrow{K_2Cr_2O_7,\ H_2SO_4}$
d. $CH_3CH_2CH(OH)CH_3 \xrightarrow{K_2Cr_2O_7,\ H^+}$

40. **a.** methoxyethane, ethyl methyl ether
b. ethoxybenzene, ethyl phenyl ether
c. The IUPAC name (ethenoxyethene) is not commonly used; the common name is divinyl ether (or vinyl ether).
d. The IUPAC name (dimethylmethoxydimethyl-methane) is not commonly used; the common name is diisopropyl ether (or isopropyl ether).

41. **a.** butanamine or butyl amine
b. ethanamine or ethylamine

LESSON 23.3

42. **a.** propanone
b. ethanal
c. 3-methylbutanal
d. 3-hexanone
e. 2-phenylethanal
f. pentanoic acid

43. **a.** CH_3CHO
b. CH_3COOH
c. $CH_3CH_2CH_2COOH$
d. $CH_3CH_2COCH_3$

23.4 Polymers

44. Different samples of a polymer such as polyethylene can have different properties. Explain.

***45.** Draw the structure of the repeating units in a polymer that has the following monomers:

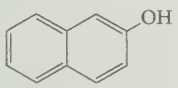
a. 1-butene
b. 1,2-dichloroethene

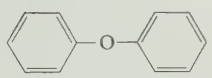
Understand Concepts

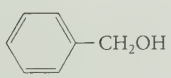
46. Write a general formula for each type of compound.

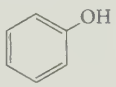
a. halocarbon
b. ketone
c. aldehyde
d. ester
e. amide
f. ether

47. Place the following compounds in order from lowest boiling point to highest boiling point. Molar masses are given in parentheses.





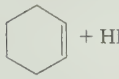




a. CH_3CHO (44 g)
b. CH_3CH_2OH (46 g)
c. $CH_3CH_2CH_3$ (44 g)

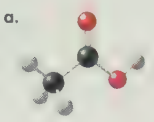
48. Write the structure and name of the expected products for each reaction.

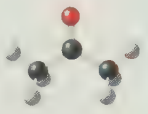
a. $CH_3COOH + CH_3OH \xrightarrow{H^+}$
b. $CH_3CH_2CH_2COOCH_2CH_3 + H_2O \xrightarrow{H^+}$
c. $CH_3CH_2OH \xrightarrow[H^+]{K_2Cr_2O_7}$

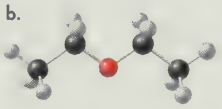


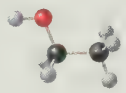
49. Explain why a carbon–carbon double bond is nonpolar, but a carbon–oxygen double bond is very polar.

***50.** Classify each compound as an alcohol, a phenol, or an ether.



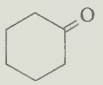






a. 
b. 
c. 
d. 
e. CH_3CH_2CHOH with CH_3 branch
f. $CH_3CH_2OCH_3$

51. Explain why 2-methyl-1-propanol can be oxidized, but 2-methyl-2-propanol cannot be oxidized.



52. Write the structural formulas for the products of these reactions.

a. $CH_3CH_2CH{=}CH_2 + Cl_2 \longrightarrow$
b. $CH_3CH_2CH{=}CH_2 + Br_2 \longrightarrow$
c.  $+ HBr \longrightarrow$

***53.** For each compound pictured below, identify the functional group and name the compound. The red atoms represent oxygen.

a. 
c. 
b. 
d. 

54. Write the name and structure for the alcohol that must be oxidized to make each carbonyl compound.

a. HCHO
c. $CH_3CH(CH_3)CHO$
b. CH_3CCH_3 (O)
d. 

55. Write the structures of the expected products for the following reactions:

a. $CH_3CH_2COOCH_2CH_3 + NaOH \longrightarrow$
b. CH_3COO–  $+ KOH \longrightarrow$
c. $CH_3CH_2COOCH_2CH_2CH_3 + H_2O \xrightarrow{H^+}$
d. $CH_3CH_2COOCH_2CHCH_3 + H_2O \xrightarrow{HCl}$ (CH_3 branch)

ASSESSMENT

LESSON 23.4

44. The properties of polyethylene vary with the length of the chains.

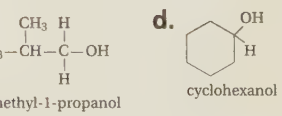
45. **a.** $-CH_2-CH(CH_2CH_3)-$ **b.** $-CH(Cl)-CH(Cl)-$

UNDERSTAND CONCEPTS

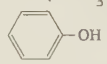
46. **a.** RX **b.** RCOR **c.** RCHO **d.** RCOOR **e.** ROR

47. c, a, b

48. **a.** CH_3COOCH_3 (methyl ethanoate or methyl acetate) + H_2O
b. $CH_3CH_2CH_2COOH$ (butanoic acid) + CH_3CH_2OH (ethanol)
c. CH_3CHO (ethanal)



49. Both atoms in a carbon-carbon double bond have the same electronegativity value, so the bond is nonpolar. Because oxygen is more electronegative than carbon, a carbon-oxygen bond is very polar.



50. **a.** phenol
b. ether
c. alcohol
d. phenol
e. alcohol
f. ether

51. 2-methyl-1-propanol is a primary alcohol, which is easily oxidized. The carbon atom attached to the hydroxy group loses a hydrogen atom in the process. 2-methyl-2-propanol is a tertiary alcohol, which does not have a hydrogen atom present on the carbon atom attached to the hydroxy group. Thus, 2-methyl-2-propanol cannot be oxidized.

52. **a.** $CH_3CH_2CCl(Cl)-CH_2$ **b.** $CH_3CH_2CBr(Br)-CH_2$ **c.** 

53 **a.** carboxyl group, ethanoic acid (acetic acid)
b. ether, diethyl ether (ethyl ether)
c. ketone (carbonyl group), propanone (acetone)
d. alcohol (hydroxyl group), ethanol (ethyl alcohol)

54. **a.** CH_3OH
methanol
b. $CH_3-CH(OH)-CH_3$
2-propanol
c. $CH_3-CH(CH_3)-C(H)(OH)-H$
2-methyl-1-propanol
d. 
cyclohexanol

55. **a.** $CH_3CH_2COO^-Na^+$, CH_3CH_2OH
b. $CH_3COO^-K^+$, 
c. CH_3CH_2COOH, $CH_3CH_2CH_2OH$
d. CH_3CH_2COOH, $CH_3CH(CH_3)CH_2OH$

Answers

THINK CRITICALLY

56. a. $CH_3COOCH_3 + H_2O \xrightarrow{HCl}$
methyl ethanoate water

$$CH_3-\overset{\overset{O}{\|}}{C}-OH + CH_3OH$$
ethanoic acid methanol

b. $CH_3CH_2COOCH_2CH_2CH_3 + H_2O \xrightarrow{NaOH}$
propyl butanoate water

$$CH_3CH_2-\overset{\overset{O}{\|}}{C}-O^-Na^+ + CH_3CH_2CH_2OH$$
sodium butanoate 1-propanol

c. $HCOOCH_2CH_3 + H_2O \xrightarrow{KOH}$
ethyl methanoate water

$$H-\overset{\overset{O}{\|}}{C}-O^-K^+ + CH_3CH_2OH$$
potassium methanoate ethanol

57. The chemical properties (and toxicity) of organic compounds are determined by the compound as a whole. As a substituent in a molecule, a phenyl group does not have the same properties as benzene.

58. The oxygen atom in diethyl ether polarizes the small molecule. This enables diethyl ether to dissolve in water, which is also polar. The large dihexyl ether molecule has large nonpolar parts and does not dissolve. Because propane is nonpolar, it is less soluble in water than diethyl ether.

59. The alcohol molecules form hydrogen bonds with one another, resulting in a higher boiling point. They also form hydrogen bonds with water molecules, causing 1-butanol to be more soluble than diethyl ether. (Although diethyl ether is polar, 1-butanol has greater polarity.)

60. Acetaldehyde is polarized by its carbonyl oxygen, forming stronger intermolecular attractions. Propane, a nonpolar compound, has weak intermolecular attractions. Thus, propane molecules are more easily liberated from the liquid state.

61. Ethanoic acid (two carbons long) is more soluble in water than decanoic acid (ten carbons long).

62. Substitution of an alkane by a halogen, for example, usually gives a mixture of products. Addition to a double bond or a triple can give a single addition product.

63. cadaverine, $H_2N(CH_2)5NH_2$; putrescine, $H_2N(CH_2)4NH_2$
Both compounds are amines.

Think Critically

56. Apply Concepts Draw the structures of the expected products and name the reactants and products for each reaction below.

a. $CH_3COOCH_3 + H_2O \xrightarrow{HCl}$

b. $CH_3CH_2COOCH_2CH_2CH_3 + H_2O \xrightarrow{H^+}$

c. $HCOOCH_2CH_3 + KOH \longrightarrow$

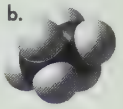
***57. Draw Conclusions** Benzene is poisonous and a proven carcinogen. Yet many compounds containing benzene rings, such as benzaldehyde, are common in the foods you eat. Why are some organic compounds with phenyl groups safe to eat?

58. Compare Explain why diethyl ether is more soluble in water than dihexyl ether. Would you expect propane or diethyl ether to be more soluble in water? Why?

59. Compare Explain why 1-butanol has a higher boiling point than diethyl ether. Which compound would you expect to be more soluble in water? Why?

60. Evaluate Propane ($CH_3CH_2CH_3$) and acetaldehyde (CH_3CHO) have the same molar mass, but propane boils at −42°C and acetaldehyde boils at 21°C. Account for this difference.

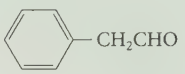
***61. Compare and Contrast** How would you expect the water solubility of ethanoic and decanoic acids to compare?



62. Infer The processes used to synthesize many organic compounds often use compounds that contain double or triple bonds as reactants. Explain why using unsaturated reactants might be advantageous over using saturated reactants.

***63. Classify** Cadaverine (1,5-pentanediamine) and putrescine (1,4-butanediamine) are unpleasant-smelling compounds that are formed by bacteria in rotting flesh. Draw their structures. What class of organic compounds are these two chemicals?

64. Graph Use the data in Table 23.3 to make a graph of boiling point versus number of chlorine atoms for the five compounds listed in the table. Is the graph a straight line? Use the graph to describe the relationship between boiling point and degree of halogen substitution.

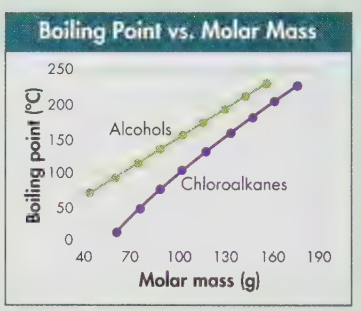


65. Apply Concepts For the following structures, write a chemical equation showing how to produce the compound.

a. 

b. 

***66. Infer** Tetrahydrofuran (THF) is an important industrial organic solvent. THF is a cyclic ether containing four carbon atoms in the ring. Draw a structural formula of this cyclic ether.



67. Predict Write structures and names of the organic products obtained when the following compounds react with Fehling's reagent.

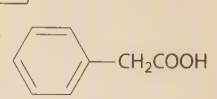
a. 

b. CH_3CHCHO
CH_3

c. CH_3CHCH_2CHO
CH_3

68. Interpret Graphs The graph shows the boiling points of the C_2–C_{10} straight-chain 1-hydroxy alcohols and straight-chain 1-chloroalkanes plotted versus their molar masses.

a. Explain why the boiling points of the alcohols are consistently higher than those of the chloroalkanes of similar molar mass.



b. Why does the gap in boiling point between the alcohols and chloroalkanes decrease with increasing chain length?

64. No, the graph is not a straight line. Boiling point increases as the degree of halogen substitution increases, but less drastically for each subsequent halogen substitution.

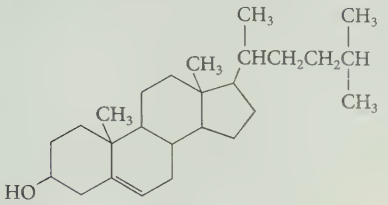
65. a. $CH_4 + Cl_2 \xrightarrow{\text{UV light}} CH_3Cl + HCl$

b. $CH_2{=}CH_2 + H_2 \xrightarrow{Pt} CH_3CH_3$

66. 

67. a. 
2–phenylethanoic acid

b. $CH_3CHCOOH$
CH_3
2–methylpropanoic acid



c. CH_3CHCH_2COOH
CH_3
3–methylbutanoic acid

68. a. Hydrogen bonding between alcohol molecules leads to higher boiling points relative to the chloroalkanes.

b. The boiling point gap decreases as the contribution of molar mass to the boiling points becomes more important.

Enrichment

*69. **Interpret Diagrams** Cholesterol is a compound in your diet and is also synthesized in the liver. Sometimes it is deposited on the inner walls of blood vessels, causing hardening of the arteries. Describe the structural features and functional groups of this important molecule.

70. **Propose a Solution** Hydrocarbons from petroleum are an important source of raw material for the chemical industry. Using reactions covered in this chapter, propose a scheme for the synthesis of ethylene glycol, a major component of antifreeze, from petrochemical ethene.

*71. **Draw Conclusions** Human hair is composed of long-chain polymers. Some of the monomers in these polymers contain sulfur atoms. When two sulfur atoms are adjacent to one another, they form strong, covalent disulfide (S—S) bonds that can link two polymer molecules together. The location of these bonds between the hair polymers affects how curly or straight the hair is and helps to hold the polymers in their shape. Waving lotion that is used in permanent waves is a reducing agent, and neutralizing agent is an oxidizing agent. Using this information, explain in terms of chemistry how a permanent wave can change the shape of hair. Describe what chemical steps should be taken to change the shape of someone's hair from straight to curly.

72. **Infer** Which of the following monomers can be used to produce the addition polymer $+CF_2+_x$: $CH_2{=}CF_2$, $CH_2{=}CHF$, CF_4, $CF_2{=}CF_2$, or $CHF{=}CHF$?

73. **Analyze Data** An unidentified compound of molecular formula $C_5H_{10}O$ produced a red precipitate when treated with Fehling's reagent. Further testing showed that the compound does not contain a hydrocarbon ring. Write structural formulas for all of the compounds that this unknown substance might be.

Write About Science

74. **Research a Problem** Methyl tert-butyl ether (MTBE) is a commonly used gasoline additive. Recently, regulatory agencies have begun to limit its use. Write a paragraph about MTBE, in which you explain the function of MTBE in gasoline and why its use is now limited.

75. Connect to the **BIG**IDEA Acetylsalicylic acid (aspirin) and ibuprofen are both active ingredients of over-the-counter pain relievers. They work by preventing certain proteins from sending pain signals to the brain. Look up the structures of these two active ingredients. Write a short report, in which you compare the structures and functional groups of the two compounds.

CHEMYSTERY

The Toothpaste Terror

Manufacturers include moistening agents in their toothpaste formulations. The most common moistening agent in toothpaste is glycerol. Usually glycerol is listed as glycerin on toothpaste ingredient labels. Glycerol is an alcohol with three hydroxy groups, which help keep the toothpaste moist by forming hydrogen bonds with water molecules in the air. Because glycerin has a sweet taste, it also sweetens the toothpaste.

*76. **Compare** Counterfeiters have been known to manufacture cheap toothpaste by substituting diethylene glycol for glycerol. Like glycerol, diethylene glycol is a moistening agent, but it is also toxic. Compare the structures of diethylene glycol and glycerol.

77. Connect to the **BIG**IDEA Often there is more than one moistening agent in toothpaste. Look at the ingredient list on your toothpaste container. Are there any other alcohols besides glycerol that may serve as moistening agents? Search the Internet to find the structures of each alcohol, and identify the number of hydroxy groups.

ASSESSMENT

CHEMYSTERY **SUMMARIZE** After students have read through the CHEMystery, call on volunteers to summarize which properties of glycerol make it a practical application for keeping toothpaste moist. Have students classify glycerol according to its proper functional groups. **Ask** Given what you know about the functional groups of this product, how should Yani have cleaned the mirror in order to quickly dissolve the toothpaste? *(Sample answer: Clean it off with a wet cloth, since it is water soluble.)*

CHEMystery Answers

76. The two molecules are similar in size. Diethylene glycol has four carbons, and glycerol has three carbons. Diethylene glycol is an ether with two hydroxy groups. Glycerol has three hydroxy groups.

77. Two common alcohols found in toothpaste are sorbitol (6 hydroxy groups) and propylene glycol (2 hydroxy groups).

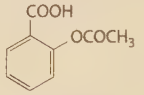
Answers

ENRICHMENT

69. Cholesterol is an alcohol with a hydroxy group on a cycloalkane. It has four nonaromatic rings. It has a double bond in one of its rings, as well as a large alkyl group, making the molecule nonpolar.

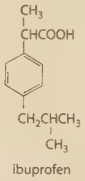
70. $CH_2CH_2(g) + Br_2(l) \rightarrow CH_2BrCH_2Br(l)$
$CH_2BrCH_2Br(l) + 2NaOH(aq) \rightarrow CH_2OHCH_2OH(l) + 2NaBr(aq)$

71. Waving lotion reduces —S—S— bonds to —SH bonds. Hair can be placed in curlers to form the hair in the desired shape. The neutralizing agent is an oxidizing agent that reforms —S—S— bonds, locking the hair into its curly shape. Similar steps could be used to straighten curly hair.



72. $CF_2{=}CF_2$

73. $CH_3CH_2CH_2CH_2CHO$; $CH_3CH_2CH(CH_3)CHO$; $CH_3CH(CH_3)CH_2CHO$; $CH_3C(CH_3)_2CHO$



WRITE ABOUT SCIENCE

74. Engines knock when gasoline burns too soon or too quickly. MTBE replaced tetraethyl lead as an anti-knocking additive. MTBE from leaking storage tanks and fuel spills contaminates groundwater.

75. Students' answers should compare the structures and functional groups of the following two compounds.

acetylsalicylic acid

ibuprofen

95. b and c

Cumulative Review

***78.** What is the maximum number of orbitals in the *p* sublevel of an atom?
a. 1 **b.** 3 **c.** 5 **d.** 9

79. Using electron dot structures, illustrate the formation of F^- from a fluorine atom and OH^- from atoms of hydrogen and oxygen.

80. Calculate the mass, in grams, of one liter of SO_2 at standard temperature and pressure.

81. A sample of 1.40 L of nitrogen gas in a sealed container at 25.0°C and 1.00 × 10^2 kPa is heated to 68.7°C. What is the new pressure?

***82.** Sodium carbonate is often sold as the anhydrous compound [$Na_2CO_3(s)$] or as the decahydrate [$Na_2CO_3{\cdot}10H_2O(s)$]. If the price per kilogram of the anhydrous and decahydrate forms are the same, which compound is the better value?

83. Assume that water enters a power plant at 20°C and leaves at 30°C. Will the amount of dissolved oxygen in the water be greater entering or leaving the plant?

84. A solution is made by diluting 250 mL of 0.210*M* $Ca(NO_3)_2$ solution with water to a final volume of 450 mL. Calculate the molarity of $Ca(NO_3)_2$ in the diluted solution.

85. In a saturated solution containing undissolved solute, the solute is continually dissolving, but the solution concentration remains constant. Explain this statement.

***86.** A 500-g aluminum tray at 22°C is heated to 180°C in an oven. How many kJ of heat does the aluminum tray absorb if the specific heat of aluminum is 0.90 J/(g·°C)?

87. Predict the direction of shift in the equilibrium position for each change in conditions.

$2NO_2(g) \rightleftharpoons 2NO(g) + O_2(g)$

a. O_2 partial pressure decrease
b. total pressure increase
c. O_2 partial pressure increase
d. NO partial pressure increase

***88.** List these K_a values for weak acids in order of increasing acid strength.
a. 3.5×10^{-6}
b. 2.7×10^{-3}
c. 1.5×10^{-5}
d. 6.6×10^{-5}

89. Assign an oxidation number to each atom in these compounds.
a. $NaNO_2$
b. $CoSO_4$
c. SeO_2
d. $Zn(OH)_2$
e. K_2PtCl_4

90. Solid sodium borohydride ($NaBH_4$) is being studied as a possible source of hydrogen fuel for hydrogen-powered vehicles. The borohydride reacts with water to produce hydrogen gas and sodium metaborate. Identify which atoms of the reactants are oxidized, which atoms are reduced, and which atoms are unaffected in this reaction.

$NaBH_4(s) + 2H_2O(l) \longrightarrow 4H_2(g) + NaBO_2(aq)$

91. What is the source of the electrical energy produced in a voltaic cell?

***92.** At which electrode in an electrolytic cell does reduction always occur? What is the charge on this electrode?

93. Draw a condensed structural formula for each compound.
a. 1,2-dimethylcyclobutane
b. 2-methyl-2-pentene
c. 2-butene
d. 2-pentyne
e. 2-methylhexene

***94.** Is petroleum or coal most likely to be a good source of aromatic compounds?

95. Which of these statements applies to ethene?
a. saturated hydrocarbon
b. H—C—H bond angle of 120°
c. alkene
d. aromatic compound

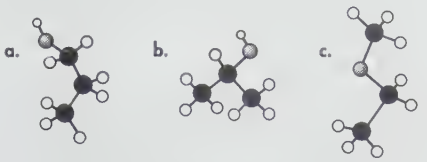
Standardized Test Prep for Indiana

Standard C.4.5

Select the choice that best answers each question or completes each statement.

1. The acid-catalyzed hydrolysis of an ester gives a carboxylic acid and
   (A) an amine. **(C)** an alcohol.
   (B) an ether. **(D)** an alkene.
2. Ethane, methanal, and methanol have similar molar masses. Which series lists the compounds in order of increasing boiling point?
   (A) ethane, methanal, methanol
   (B) methanal, methanol, ethane
   (C) methanol, methanal, ethane
   (D) ethane, methanol, methanal
3. A carbonyl group is characterized by a
   (A) carbon–carbon double bond.
   (B) carbon–oxygen double bond.
   (C) carbon–nitrogen single bond.
   (D) carbon–oxygen single bond.

The lettered choices below refer to Questions 4–7. A lettered choice may be used once, more than once, or not at all.



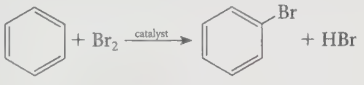
(A) alcohol **(C)** carboxylic acid
(B) ketone **(D)** ether

To which class of organic compounds does each of the following compounds belong?

4. CH_3CH_2COOH
5. $CH_3CH_2CH_2OH$
6. $CH_3CH_2OCH_3$
7. CH_3COCH_3

Use the following models with Question 8.

a. b. c.



8. The molecular formula for each compound is C_3H_8O. Write the name for each compound.
9. There are two compounds with a carbonyl group that have the molecular formula C_3H_6O. Write a complete structural formula for each compound. Name each compound.

Tips for Success

Eliminate Wrong Answers If you don't know which choice is correct, eliminate those you know are wrong. If you can rule out some choices, you'll increase your chances of choosing the correct answer.

Characterize the reactions in Questions 10–14 as an addition, esterification, oxidation, polymerization, or substitution reaction.

10. $CH_3CHO \xrightarrow[H_2SO_4]{K_2Cr_2O_7} CH_3COOH$
11. $CH_2{=}CH_2 + HCl \longrightarrow CH_3CH_2Cl$
12. $CH_3CO_2H + CH_3CH_2OH \xrightarrow{H^+} CH_3COOCH_2CH_3 + H_2O$
13. $x CH_2{=}CH_2 \longrightarrow H\text{-}(CH_2\text{-}CH_2)_x\text{-}H$
14.  + Br_2 $\xrightarrow{\text{catalyst}}$ + HBr

For each question there are two statements. Decide whether each statement is true or false. Then decide whether Statement II is a correct explanation for Statement I.

	Statement I		Statement II
15.	The addition of hydrogen to an alkene is a reduction reaction.	BECAUSE	The addition of hydrogen to any molecule is a reduction reaction.
16.	Aldehydes are easily oxidized.	BECAUSE	Oxidation of aldehydes produces alcohols.
17.	Ethanol (CH_3CH_2OH) is immiscible in water in all proportions.	BECAUSE	Ethanol molecules can form hydrogen bonds with other ethanol molecules.

Materials List

For the Student

Small-Scale Lab, p 849
- chicken egg
- ruler
- balance

Quick Lab, p 856
- cardboard tube from paper-towel roll
- felt-tip markers, two colors
- metric ruler
- thumbtack
- 10 toothpicks

For the Teacher

Class Activity, p 839
- photographs of living and nonliving things

Teacher Demo, p 842
- foam balls and toothpicks or molecule kit

Teacher Demo, p 843
- hot-water bath
- 4–6 mL of 1% carbohydrate solution
- 2 test tubes
- distilled water
- 2–3 mL of Benedict's reagent
- dropper
- samples of mono- and polysaccharides

Teacher Demo, p 845
- models of amino acids

Teacher Demo, p 846
- thigh bone from cooked poultry
- 1M HCl
- beaker

Class Activity, p 851
- butter
- regular margarine
- low-calorie margarine
- 3 test tubes
- balance
- warm-water bath

PearsonChem.com

All organisms, including you and your classmates, are made of the same types of molecules: carbohydrates, proteins, lipids, and nucleic acids.

IN ACADEMIC STANDARDS for SCIENCE

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.
- Clearly communicate their ideas and results of investigations verbally and in written form using tables, graphs, diagrams, and photographs.

Focus on ELL

1 CONTENT AND LANGUAGE Write the chapter title on the board. Underline the word *Life*. Ask volunteers to explain their ideas of what life is. Have students skim through the lesson titles, essential questions, and CHEMystery and identify words that are unfamiliar to them. Group students who are unfamiliar with the same word. Have each group complete a Frayer model diagram for this word, with a definition, characteristics, an example, and a nonexample.

BEGINNING

LOW Create a symbol or drawing to represent the word.

HIGH Write the word and introduce it to the class by pointing to it and slowly saying it aloud.

INTERMEDIATE: LOW/HIGH Brainstorm examples and nonexamples with the class.

ADVANCED: LOW/HIGH Write the definition and present it to the class. Explain to the class how the examples represent the word.

BIGIDEA

CHEMISTRY AS THE CENTRAL SCIENCE

Essential Questions:

1. *What are the characteristics of the four main types of biological molecules?*
2. *What is the function of anabolism and catabolism in a cell?*

CHEMYSTERY

Phenyl-what?

Do you ever look at the labels on food and wonder what they mean? In the United States, the Food and Drug Administration (FDA) regulates the requirements for how foods are labeled. Information that you might see on foods includes a nutrition label, the quantity of the food, the ingredients the food contains, and an expiration date.

Some food labels also contain warnings about the ingredients in the food. Some labels warn you about something common, like nuts or milk. But other times the warning may leave you wondering what it means. The warning on the label shown here says the product "Contains phenylalanine." What is phenylalanine? Why would people need to know that phenylalanine is in their food?

▶ Connect to the BIGIDEA As you read about molecules involved in life's processes, think about how the chemistry of these molecules is central to living things.

Introduce the Chapter

CONNECTIONS TO THE REAL WORLD Students may not have thought about the chemical nature of the food they eat. Use the following activity to help students relate food and chemical concepts they will study in this chapter.

Activity *You will need to bring into class a variety of food nutrition panels and foods representing each of the four main types of biological compounds.* **Ask** Where does your body get the chemicals it needs to live and grow? *(from the food you eat)* Have students examine each food label and name different chemicals. Engage them in discussing possible benefits the body gets from the different chemicals. Discuss how the fresh fruits and vegetables or other foods you have brought in provide nutrients people need for biological processes.

UbD

Understanding by Design

Students are building toward understanding how chemistry is the central science by learning about the chemistry of life.

PERFORMANCE GOALS At the end of Chapter 24, students will be able to answer the essential questions by applying their knowledge of the chemistry of life. Students will also be able to explain the importance of Earth's carbon, oxygen, and nitrogen cycles to biological processes.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** What do you think the term *biological molecule* means? *(Sample answer:* Bio- *means "life." A biological molecule is a molecule produced by living things.)* **Ask** What are some processes that occur in the human body that require energy? *(Sample answers: breathing, changing food into chemicals the body can use, maintaining a steady condition in the body)*

BIGIDEA Use the photo of students standing in a forest to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by leading students in a discussion of ways the people and trees around them are alike. Explain that all organisms have properties that depend on chemical processes. **Ask** What are some ways that chemical processes help the people and trees survive? *(Sample answer: Trees and people grow and reproduce.)* Point out that these processes require chemicals that people and trees obtain from the environment.

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of chemistry as the central science by engaging students in a discussion of food ingredient labels. Explain that understanding the chemistry of food is important. As a hint about why people might need to know that phenylalanine is in food, point out that the problem is so important that the warning on the label is in bold type. Encourage students to think about why this information would be important to some people.

LESSON 24.1

Key Objectives

24.1.1 IDENTIFY the two major cell types that occur in nature.

24.1.2 IDENTIFY the compound that is reduced during photosynthesis and the compounds formed.

Additional Resources

- Reading and Study Workbook, Lesson 24.1

PearsonChem.com

Engage

CHEMISTRY & YOU **Ask** What gases may have dominated Earth's early atmosphere? *(Studies suggest the following: CO_2, CH_4, H_2, NH_3, N_2, and H_2O.)* **Ask** What life-supporting gas does photosynthesis produce? *(oxygen)* **Ask** What types of organisms photosynthesize? *(many types of bacteria and almost all plant species)*

Activate Prior Knowledge

Encourage students to share what they know about the flow of energy and matter through an ecosystem. Remind students that the movement of both through an ecosystem is the result of chemical processes that take place in the cells of living organisms.

Foundations for Reading

BUILD VOCABULARY The word *photosynthesis* has two Greek roots. *Phot* means "light," and *suntithenai* means "to put together." Photosynthesis uses light to combine carbon dioxide and water into glucose.

24.1 A Basis for Life

CHEMISTRY & YOU

Q: *Where do fish get their oxygen?* All animals need oxygen to survive. Most fish obtain oxygen as water flows across their gills. We breathe in oxygen from the air around us. The air you breathe is composed mainly of nitrogen (N_2) and oxygen (O_2). Earth's early atmosphere may have been very different, with very little oxygen, and most inhospitable to life. It is thought that the atmosphere changed over time. In this lesson, you will learn how oxygen in both the air and water is produced.

Key Questions

- ***What are the two major types of cells that occur in nature?***
- ***What compound is reduced during photosynthesis? What compounds are formed?***

Vocabulary

- photosynthesis

The Structure of Cells

What are the two major types of cells that occur in nature?

Life! You are certainly familiar with it, but what does it really mean? Until recently, life was defined as the ability of an organism to grow and to reproduce its own kind. However, recent discoveries made at the fringes of life seem to blur this simple definition. As difficult as it is to define life, you can generally regard tiny structures called cells as the fundamental units of life.

Organisms are composed of as few as one cell or as many as billions of cells. **Two major cell types occur in nature: prokaryotic cells and eukaryotic cells.** The prokaryotic cell is the more ancient of the two. Microscopic examination of fossilized remains shows that prokaryotic cells were present on Earth at least 3 billion years ago. Eukaryotic cells did not appear until about 1 billion years ago. Figure 24.1 shows both types of cells.

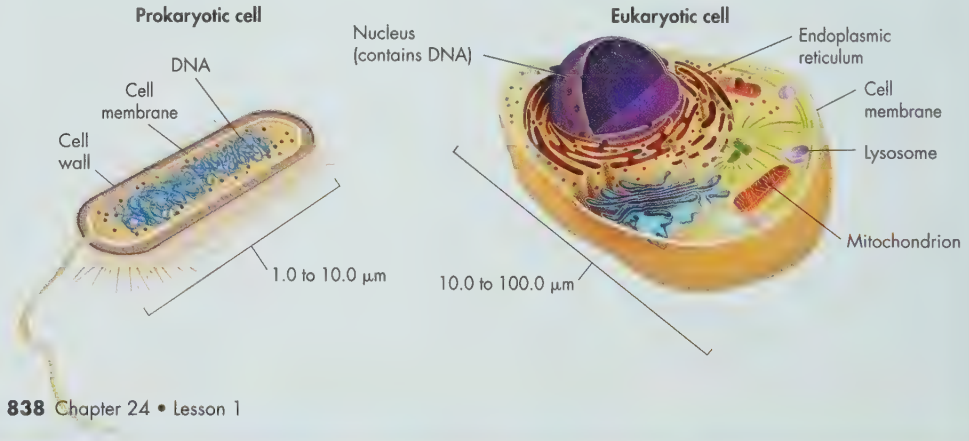

Figure 24.1 Cell Types
Typical prokaryotic and eukaryotic cells are shown here. Note that only the eukaryotic cell has a nucleus.
Compare and Contrast ***How do prokaryotic and eukaryotic cells compare in size?***

Focus on ELL

1 CONTENT AND LANGUAGE Review vocabulary terms such as *organelles*, *prokaryotic cells*, *eukaryotic cells*, and *chloroplast* by assigning each term to a group. Have each group research the definition of the term, create a drawing of what the term refers to, and present the drawing to the class. Encourage students to use any one of the vocabulary methods they have learned in this course.

2 FRONTLOAD THE LESSON Access students' prior knowledge by asking them what they already know about prokaryotic and eukaryotic cells. Have several biology books available for students to reference. Discuss why understanding the structure of cells is important for a chemist that studies biological molecules.

3 COMPREHENSIBLE INPUT Project Figure 24.3 on a dry-erase board, and provide students with printed copies. Write the chemical formulas of reactants and products associated with each process beside its descriptive label.

Both eukaryotic and prokaryotic cells contain all the chemicals necessary for life, encased in a cell membrane. The cell membrane is a sack that holds the contents of a cell and acts as a selective barrier for the passage of substances into and out of the cell. Eukaryotic cells are considerably larger and more complex than prokaryotic cells, but the chemical processes carried out by both types of cells are very similar.

One major feature that distinguishes eukaryotic cells from prokaryotic cells is that eukaryotic cells contain membrane-enclosed organelles. Organelles, meaning little organs, are small structures suspended in the interior cellular fluid, or cytoplasm. The organelles are the sites of many specialized functions in eukaryotic cells. For example, the nucleus, a structure that is important in eukaryotic cell reproduction, is not present in prokaryotic cells. Mitochondria (singular: mitochondrion) are the source of cellular energy in eukaryotic cells that use oxygen. Mitochondria are often referred to as the powerhouses of the cell. Lysosomes are the sites for the digestion of substances taken into a cell. Yet another membrane-enclosed structure in eukaryotic cells is the highly folded, netlike endoplasmic reticulum (ER). Among its various functions, the ER serves as an attachment site for ribosomes. The ribosomes, small organelles that are not membrane-enclosed, are the sites where essential substances called proteins are made.

The Energy and Carbon Cycle

What compound is reduced during photosynthesis? What compounds are formed?

Organisms must have energy to survive. The ultimate source of this energy is the sun. Cells of green plants and certain algae contain organelles called chloroplasts that are able to capture solar energy and make food. Within a chloroplast is a light-capturing system of membranes, shown in Figure 24.2, that converts light energy into chemical energy by a process called **photosynthesis.** In addition to sunlight, photosynthetic organisms require carbon dioxide and water. **Photosynthesis uses the energy from sunlight to reduce carbon dioxide to compounds that contain C—H bonds, mainly in the form of glucose ($C_6H_{12}O_6$).** The following equation summarizes the process:

$$\underset{\text{Carbon dioxide (carbon in more oxidized state)}}{6CO_2} + \underset{\text{Water}}{6H_2O} + \underset{\text{from sunlight}}{\text{Energy}} \longrightarrow \underset{\text{Glucose (carbon in more reduced state)}}{C_6H_{12}O_6} + \underset{\text{Oxygen}}{6O_2}$$

Figure 24.3 on the next page illustrates the relationship between photosynthesis and the carbon compounds used by all organisms. In the energy and carbon cycle, photosynthetic organisms produce necessary carbon compounds. Animals, which do not carry out photosynthesis, get these carbon compounds by eating plants or by eating animals that feed on plants. Both plants and animals get energy by unleashing the energy stored in the chemical bonds of these carbon compounds. The nutrients are oxidized back to carbon dioxide and water in the process.

$$\underset{\text{Glucose (carbon in more reduced state)}}{C_6H_{12}O_6} + \underset{\text{Oxygen}}{6O_2} \longrightarrow \underset{\text{Carbon dioxide (carbon in more oxidized state)}}{6CO_2} + \underset{\text{Water}}{6H_2O} + \text{Energy}$$

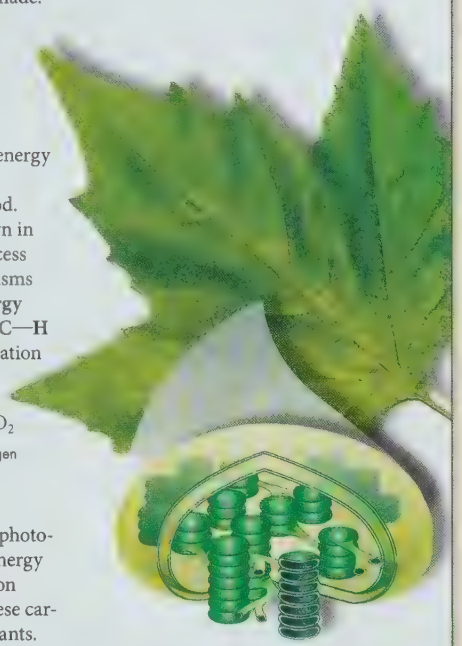

Figure 24.2 Chloroplast
The reactions of photosynthesis take place on the inner membranes and in the spaces between membranes of a chloroplast. The pigments in chloroplasts are why leaves are green in color.

Professional Development Note

Detailing Photosynthesis

Melvin Calvin (1911–1997) and others in his laboratory were important participants in tracing the chemical reactions that take place in photosynthesis. Their work was made possible by two techniques: using radioactive carbon-14 to follow carbon's path through the complex process and using chromatography to identify the products at each step.

READING STRATEGY Instruct students to read the caption with each figure in this lesson. Have students read the caption and other text with Figure 24.3 and have them summarize how this diagram conveys the concept of photosynthesis and the carbon compounds used by all organisms.

Explain

The Structure of Cells

USE VISUALS Direct students' attention to Figure 24.1. Note that eukaryotic cells can vary greatly in size and shape, but they are always larger than prokaryotic cells. Point out that many metabolic reactions in eukaryotic cells are compartmentalized. **Ask** What possible advantages would organelles provide for a cell? *(Many of the chemical activities that occur in cells involve similar reactants and products. By nature, they are incompatible. If these processes are physically separated, they can proceed concurrently without conflict.)*

Class Activity

Have teams of students create a two-column chart of characteristics that distinguish living from nonliving systems. *(Living things have one or more cells; they obtain and consume energy; they respond to changing conditions; they grow and develop, and they can reproduce.)* Then present photographs of living and nonliving things and help students use their lists to classify each subject as living or nonliving.

Answers

FIGURE 24.1 Eukaryotic cells are larger than prokaryotic cells.

Extend

Connect to ENGINEERING

Have students explore the concept of why some large metropolitan cities are encouraging "green" roofs for office buildings. Students should be able to explain at least four reasons for how a green roof is beneficial to the environment.

CHEMISTRY & YOU Photosynthesis

Evaluate

The Energy and Carbon Cycle

Informal Assessment

Write the equation for photosynthesis on the board. **Ask** Should this reaction be classified as acid–base, redox, or a combination? *(redox)* Why? *(Carbon dioxide is reduced and water is oxidized.)* **Ask** Is photosynthesis endothermic or exothermic? *(endothermic)* **Ask** Which part of the plant cell specializes in the light–harvesting reactions of photosynthesis? *(the chloroplast)* Then have students complete the 24.1 Lesson Check.

Reteach

Have students examine Figure 24.3. Explain that the diagram represents the flow of energy and nutrients through Earth's biosphere, the regions on Earth where living organisms exist. Point out that energy is required to maintain the highly organized chemical environments found in living cells. **Ask** Where does the energy come from that drives the cycle? *(the Sun)* **Ask** Why are plants and other photosynthetic organisms called producers and animals called consumers? *(Photosynthetic organisms produce high-energy forms of carbon compounds that are consumed by animals.)*

CHEMISTRY & YOU

Q: *Fish, like all animals, need oxygen to survive. What process produces oxygen?*

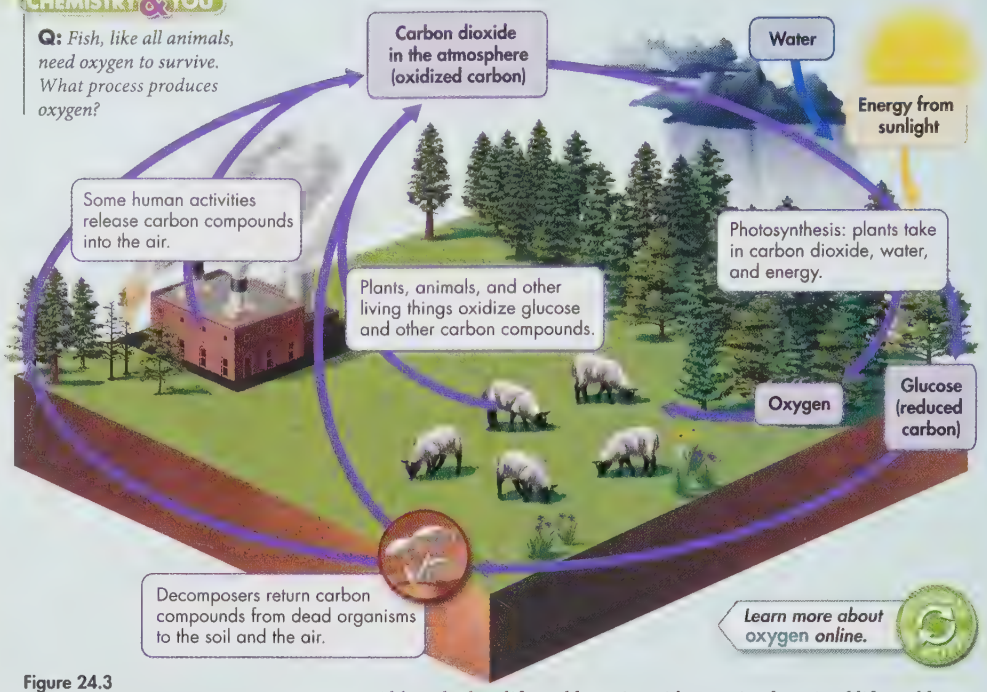

Figure 24.3
Energy and Carbon Cycles
In the energy and carbon cycle, photosynthesis and the oxidation of glucose are responsible for the major transformations and movements of carbon. Plants release oxygen into the atmosphere through photosynthesis.
Interpret Diagrams ***In which parts of the cycle is oxygen consumed?***

Although plant life could survive without animals, animal life could never survive without plants. Without photosynthesis, the supply of carbon compounds that animals need to get energy would not exist.

Oxygen is another important product of photosynthesis. Photosynthetic land-dwelling and aquatic organisms produce the oxygen found in Earth's atmosphere, oceans, and lakes. Oxygen is needed for most organisms to live. The importance of photosynthetic organisms is a major reason for the concern about the loss of such organisms through the destruction of forests.

All biological processes, including photosynthesis, are based on certain essential kinds of chemical substances. Surprisingly, the great complexity of life arises from just a few types of biological molecules. In the remainder of this chapter, you will learn about the molecular structures of the great classes of biological molecules and the roles they play in living things.

24.1 LessonCheck

1. **Identify** What two types of cells occur in nature?
2. **Review** What chemical changes occur during photosynthesis?
3. **Identify** What are the fundamental units of life?
4. **Describe** Describe the structure of a eukaryotic cell.
5. **Describe** What is the function of chloroplasts in green plants and algae?
6. **Identify** Write an equation that describes the oxidation of glucose.
7. **Explain** Explain how carbon moves through the environment.

Lesson Check Answers

1. eukaryotic cells and prokaryotic cells
2. CO_2 is reduced to glucose and oxygen is released.
3. cells
4. A eukaryotic cell has a nucleus and other membrane-enclosed organelles.
5. Chloroplasts capture solar energy and make food.
6. $6CO_2 + 6H_2O + \text{energy} \rightarrow C_6H_{12}O_6 + 6O_2$
7. Carbon moves through the environment in the carbon and energy cycle: Through photosynthesis, plants convert carbon dioxide to carbon compounds used for energy and growth; animals ingest plant products for energy, producing carbon dioxide in the process, which returns to the atmosphere.

24.2 Carbohydrates

CHEMISTRY & YOU

Q: *Why does a cow chew all day?* Cows spend most of their day chewing their food. A cow's diet is rich in cellulose, which belongs to a class of organic molecules known as carbohydrates. In this lesson, you will learn about the structures and functions of carbohydrates.

Key Question

What is the general formula of carbohydrates?

Vocabulary

- carbohydrate
- monosaccharide
- disaccharide
- polysaccharide

Figure 24.4 Carbohydrates in Food Carbohydrates are the most abundant sources of energy in food. But some sources are healthier than others. Vegetables, fruits, beans, and whole-grain pastas are a healthier source of carbohydrates than white breads, cookies, and sodas.

Classifying Carbohydrates

What is the general formula of carbohydrates?

Long-distance runners often prepare for a big race by eating a great deal of bread and pasta, a process known as carbohydrate loading. Breads and pastas are excellent sources of the family of important molecules called carbohydrates. **Carbohydrates** are monomers and polymers of aldehydes and ketones that have numerous hydroxyl groups attached; they are made up of carbon, hydrogen, and oxygen. **Most carbohydrates have the general formula $C_n(H_2O)_n$.** The name *carbohydrate* comes from the early observation that because of the formula, $C_n(H_2O)_n$, the compounds appear to be hydrates of carbon. But, carbohydrates are not true hydrates.

Carbohydrates are the main source of energy for the body. They are found in most foods, including fruits, breads, and the pasta and legumes in Figure 24.4. Carbohydrates are also in many sweets, such as cookies and pies. In this lesson, you will learn about the similarities and differences among some well-known types of carbohydrates.

Monosaccharides The simplest carbohydrate molecules are called simple sugars, or **monosaccharides.** Glucose and fructose are examples of simple sugars. Glucose is abundant in plants and animals. Glucose is the primary energy source for our bodies. Depending on the source, glucose has also been called corn sugar, grape sugar, or blood sugar. Fructose occurs in a large number of fruits and in honey. Glucose and fructose both have the molecular formula $C_6H_{12}O_6$. However, glucose has an aldehyde functional group, whereas fructose has a ketone functional group. Therefore, glucose and fructose are constitutional isomers. Both undergo many of the same reactions as ordinary aldehydes and ketones.

Focus on ELL

1 CONTENT AND LANGUAGE Write the term *polysaccharide* on the board, and pronounce it for students. Explain that this term comes from the Greek words *polys*, meaning "full" or "many," and *sakcharon*, meaning "sugar"; it is a compound formed by the linking together of simple sugar molecules.

2 FRONTLOAD THE LESSON Ask students to write down everything they ate or drank the day before. As you discuss carbohydrates, have them circle the items consumed that contained carbohydrates.

3 COMPREHENSIBLE INPUT When discussing cellulose, create a short ball-and-stick model of three units of glucose. Manipulate the model to show how the glucose units in cellulose differ from those in starch.

LESSON 24.2

Key Objective

24.2.1 CONSTRUCT the general formula for carbohydrates.

Additional Resources

PearsonChem.com

Engage

CHEMISTRY & YOU Direct students to the photograph and read the opening text. Encourage them to think about the structure of plant cells as they predict an answer to the question. Have them write their predictions in their notebooks.

Activate Prior Knowledge

Remind students of what they know about polymers. As they read this section, they should use this prior knowledge to confirm differences among different types of polysaccharides.

Answers

FIGURE 24.3 Living things consume oxygen as they oxidize glucose and other carbon compounds.

Foundations for Reading

BUILD VOCABULARY Have students make a concept map of the relationships among carbohydrates, monosaccharides, disaccharides, and polysaccharides. Encourage students to personalize their concept maps with illustrations or photographs.

READING STRATEGY Preview the chemical structures shown throughout the lesson. Review key information about functional groups and the types of reactions they can undergo.

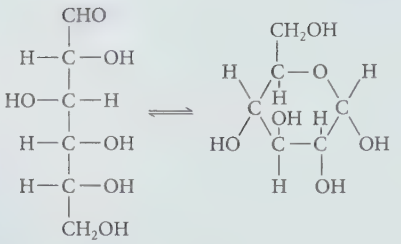
Explain

Classifying Carbohydrates

USE VISUALS Direct students to Figure 24.5. Point out that plants are mostly composed of a carbohydrate known as cellulose. **Ask** What are carbohydrates, and what is the general formula of these compounds? *(Carbohydrates are a group of organic compounds that includes simple and complex sugars. Most carbohydrates have the general formula $C_n[H_2O]_n$.)*

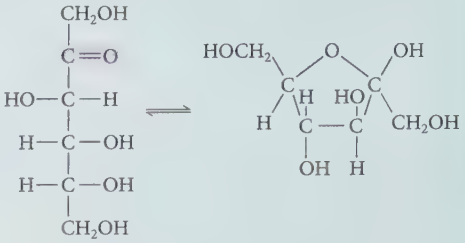
Explore

Teacher Demo



PURPOSE Students build models depicting the structures of glucose and fructose.

MATERIALS foam balls and toothpicks or molecule kit

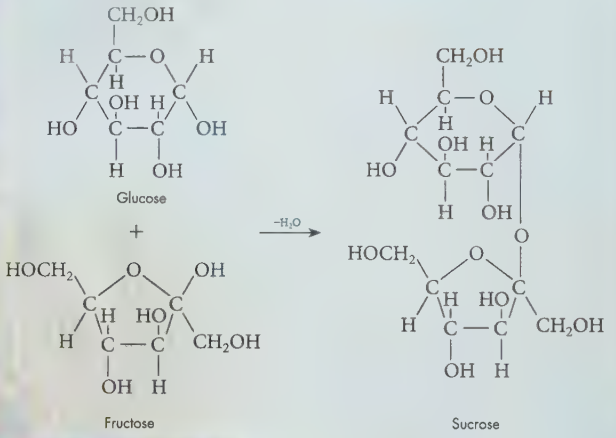


PROCEDURE Construct ball-and-stick models of glucose and fructose. Point out the functional groups. Demonstrate the cyclization of the straight-chain forms. Connect the two cyclic forms to produce a disaccharide, and note the loss of a water molecule. Point out that if this condensation reaction is allowed to continue, many monosaccharide units could join to form a polysaccharide.

ANSWER TO READING SUPPORT Monosaccharides are the building blocks of more complex sugars. A disaccharide forms from two monosaccharides. A polysaccharide forms from many monosaccharide monomers.

In aqueous solution, simple sugars such as glucose and fructose exist in a dynamic equilibrium between straight-chain and cyclic forms. The cyclic form predominates. The structures for each sugar in both forms are below.

Straight-chain and cyclic forms of glucose



Straight-chain and cyclic forms of fructose

READING SUPPORT

Build Vocabulary:
Prefixes The word *saccharide* is from the Sanskit *sarkara*, which means "sugar." The prefixes *mono-*, *di-*, and *poly-* mean one, two and many, respectively. ***How does knowing this help you remember the meanings of monosaccharide, disaccharaide, and polysaccharide?***

Note the aldehyde functional group (—CHO) on the straight-chain form of glucose and the ketone functional group (—C(=O)—) on the straight-chain form of fructose.

Disaccharides Simple sugars form the building blocks of more complex carbohydrates. The cyclic forms of two simple sugars can be linked by means of a condensation reaction. For example, the linking of glucose and fructose with the loss of a water molecule produces sucrose—common table sugar. Sugar cane plants, such as those in Figure 24.5, are a major source of sucrose. A sugar such as sucrose that forms from the condensation of two monosaccharides is known as a **disaccharide.** The reaction by which it forms is as follows:

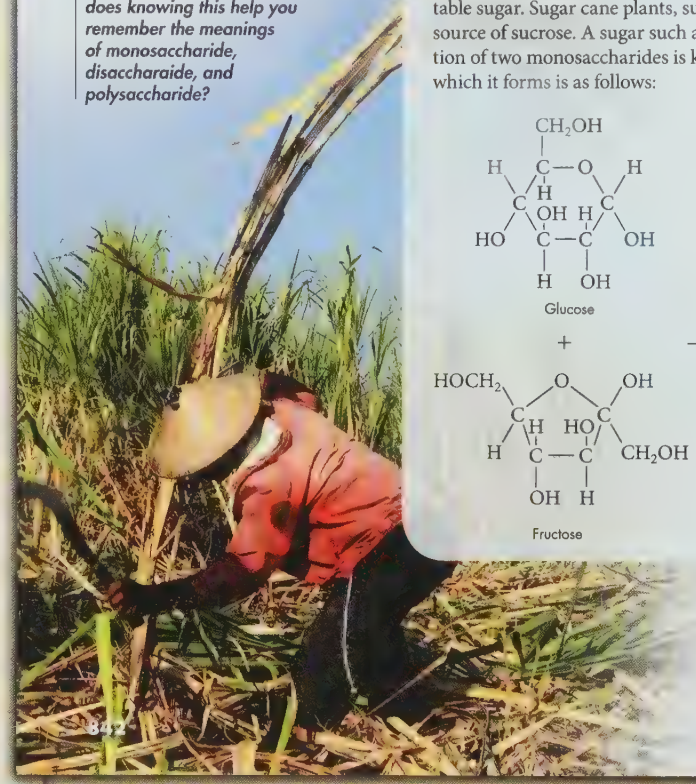


Figure 24.5 Sugar Cane
Sucrose is obtained commercially mainly from the juice of sugar cane and sugar beets. Sugar cane, shown here, grows as a tall grass and is often harvested by hand.

Professional Development Note

Glucose Testing

The ability to detect mono- and polysaccharides is an important function of clinical laboratories and at-home tests for those afflicted with diabetes mellitus. The Benedict's test is one way to test for monosaccharides. It is not specific to glucose, however, but tests the total reducing substance. Available test strips allow more precise measurement of glucose. They combine enzymes specific to glucose with indicators whose colors depend on the concentration of glucose.

Polysaccharides The formation of a disaccharide is sometimes the first step in a condensation polymerization reaction that produces extremely large molecules. The polymers produced by the linkage of many monosaccharide monomers are called **polysaccharides.** Starches, the major storage form of glucose in plants, are polysaccharide polymers that consist of glucose monomers. Figure 24.6 shows a portion of a starch molecule.

A typical linear starch molecule contains hundreds of glucose monomers. Other starches are branched molecules, each branch containing about a dozen glucose units. Glycogen, the energy source stored in the liver and muscle cells of animals, is a more highly branched molecule than plant starches. Glycogen, too, consists of glucose monomers.

Cellulose is probably the most abundant biological molecule on Earth. As you can see in Figure 24.6, cellulose also is a polymer of glucose. The orientation of the bond that links the glucose monomers in cellulose is different from the bond orientation in starch and in glycogen. Starch can be digested by most organisms and is partially soluble in water. Cellulose, however, can be digested by only a few kinds of microorganisms, such as those that live in the digestive tracts of cattle and termites. Cellulose is insoluble in water and is an important structural polysaccharide that provides form, hardness, and rigidity in plants. Plant cell walls are made of cellulose. Cotton is about 80 percent cellulose.

CHEMISTRY & YOU

Q: *A cow's diet consists mostly of cellulose. A cow's stomach contains several parts. Food enters the first part of the stomach and is then regurgitated so the cow can chew it again. The regurgitated food then goes to a later part of the stomach where special bacteria live. Why is chewing and regurgitating necessary for a cow to digest cellulose?*

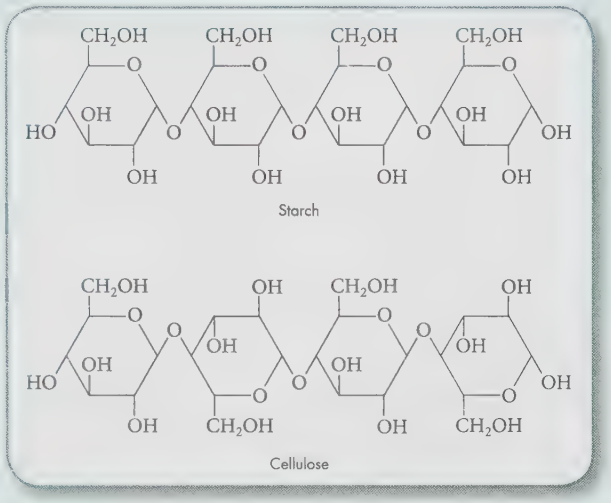

Figure 24.6 Polysaccharides Starch and cellulose are similar polymers made up of hundreds of glucose monomers. They differ in the orientation of the bond between the glucose units. Because of this difference, starch is readily digestible, but cellulose is indigestible by most organisms.
Use Models ***What are the differences between the complete structural formulas used in Figure 24.5 and the formulas used in Figure 24.6?***

24.2 LessonCheck

8. Review What is the general formula for carbohydrates?

9. Identify Where is glucose found in nature?

10. Explain How can the cyclic forms of two simple sugars be combined?

11. Compare Distinguish between the important structural features of sucrose, glucose, and fructose.

12. Describe Describe the main characteristics of monosaccharides, disaccharides, and polysaccharides.

13. Compare Starch and cellulose have different properties, but both are composed of glucose units. Explain what makes them different.

14. Review Name a source for each polysaccharide:
- **a.** starch
- **b.** cellulose
- **c.** glycogen

15. Identify What is the most abundant carbohydrate on Earth, and where is it found?

Lesson Check Answers

8. $C_n(H_2O)_n$

9. in plants and animals

10. via a condensation reaction

11. *sucrose*: disaccharide of glucose and fructose; *glucose*: monosaccharide with aldehyde functional group; *fructose*: monosaccharide with ketone functional group

12. Monosaccharides (simple sugars) can exist in straight-chain or cyclic form. Disaccharides form when two simple sugars condense. Polysaccharides are polymers of monosaccharides.

13. The orientation of the bonds that link the glucose monomers is different.

14. **a.** plants
b. plant cell walls
c. liver and muscle cells of animals

15. Cellulose; it is found in plant cell walls.

Explain

CHEMISTRY & YOU Chewing and regurgitating helps break down the cellulose, so that it can be digested by the microorganisms that live in a cow's digestive tract.

Explore

Class Activity

PURPOSE Students will classify sugars as reducing or nonreducing.

MATERIALS hot-water bath, 2–5 mL of 1% carbohydrate solution, 2 test tubes, distilled water, 4–6 mL of Benedict's reagent, dropper, samples of mono- and polysaccharides

PROCEDURE Place 2–5 mL of 1% carbohydrate solution (corn syrup) in one test tube; place distilled water in another test tube as a negative control. Add 2–3 mL of Benedict's reagent to each tube and heat in the hot–water bath for a few minutes. The Cu_2 ions in the reagent react with reducing sugars to form a brick-red cuprous oxide (Cu_2O) precipitate. The amount of precipitate formed depends on the amount of sugar present. Have students observe the formation of a red precipitate. Test a number of mono- and polysaccharides and have students classify them as reducing or nonreducing.

EXPECTED OUTCOME The precipitate indicates presence of a simple sugar.

Evaluate

Informal Assessment

Write on the board the structure of mono-, di-, and polysaccharides and give a common example of each. Then have students identify the types of elements, functional groups, and linkages found in carbohydrates. Then have students complete the 24.2 Lesson Check.

Answers

FIGURE 24.6 The complete structural formulas in Figure 24.5 include every atom in the molecule. The structural formulas in Figure 24.6 include the functional groups, but the symbols for the carbons in the ring structures are omitted as well as the symbols for the hydrogen atoms that are bonded to these carbon atoms.

LESSON 24.3

Key Objectives

24.3.1 DIAGRAM the general structure of an amino acid.

24.3.2 IDENTIFY what determines the differences in the chemical and physiological properties of peptides and proteins.

24.3.3 DESCRIBE how enzymes affect the rates of reactions in living things.

Additional Resources

PearsonChem.com

Engage

CHEMISTRY & YOU Direct students to the photograph and read aloud the text. Ask a student volunteer to explain his or her regimen for building strength. Encourage the volunteer to discuss his or her nutritional habits and strength training ritual.

Activate Prior Knowledge

Review topics that students need for success in this chapter, such as polarity, carboxyl groups, amino groups, aliphatic and aromatic hydrocarbons, and optical isomers. Then have class members discuss what they know about proteins.

24.3 Amino Acids and Their Polymers

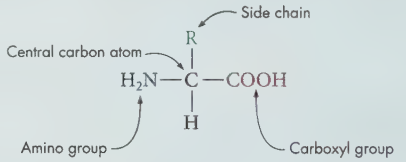
CHEMISTRY & YOU

Q: *Why do your muscles need amino acids?* Your muscles are constantly in use. For example, muscles in your stomach aid in digestion of the food you eat, and muscles in your fingers allow you to turn pages in a book or manipulate a computer mouse. Strength-building exercises can cause your muscles to become larger and stronger. This could not happen without amino acids. In this lesson, you will learn about amino acids and some of their functions.

Key Questions

- *What is the general structure of an amino acid?*
- *What determines the differences in the chemical and physiological properties of peptides and proteins?*
- *How do enzymes affect the rates of reactions in living things?*

Vocabulary



- amino acid
- peptide
- peptide bond
- protein
- enzyme
- substrate
- active site

Amino Acids

What is the general structure of an amino acid?

Many biological compounds contain nitrogen in addition to carbon, oxygen, and hydrogen. Some of the most important nitrogen-containing molecules in organisms are amino acids. In fact, the polymers of amino acids make up more than one half of the dry weight of your body.

An **amino acid** is any compound that contains an amino group ($—NH_2$) and a carboxyl group (—COOH) in the same molecule. For chemists and biochemists, however, the term is usually reserved for the 20 common amino acids that are formed and used by living organisms. **Amino acids consist of a carboxyl group, an amino group, a hydrogen, and an R group side chain that are all covalently bonded to a central carbon atom.**

The chemical nature of the side-chain group accounts for the differences in properties of the 20 amino acids. In some amino acids, the side chains are nonpolar aliphatic or aromatic hydrocarbons. In other amino acids, the side chains are neutral but polar. In still others, the side chains are acidic or basic.

Because the central carbon of amino acids is asymmetric, these compounds can exist as enantiomers. As you may recall from Lesson 22.3, enantiomers may be right- or left-handed. Nearly all the amino acids found in nature are of the left-handed, or L, form.

Table 24.1 gives the names of amino acids with their three-letter abbreviations. Examine the abbreviations. You will use them as shortcuts when you read or write about protein structure.

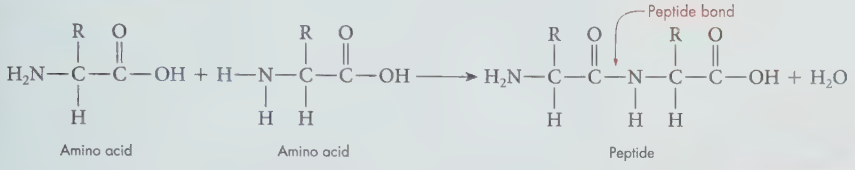
Focus on ELL

1 CONTENT AND LANGUAGE Ask students to work in pairs and scan the text for chemistry vocabulary that they have heard before, such as *acid* and *protein*. Ask students to make a list of the words and quick descriptions of the contexts in which they have heard the words.

2 FRONTLOAD THE LESSON Have students preview the chemical structures shown in the lesson text and identify familiar functional groups and reactions. Tell students to ask themselves what they already know about these groups and reactions and to predict how they might be related to proteins.

3 COMPREHENSIBLE INPUT Use fan-folded computer paper and toy springs to model the three-dimensional structures of proteins illustrated in Figure 24.8.

Table 24.1



Common Amino Acids

Name	Symbol	Name	Symbol	Name	Symbol	Name	Symbol
Alanine	Ala	Glutamine	Gln	Leucine	Leu	Serine	Ser
Arginine	Arg	Glutamic acid	Glu	Lysine	Lys	Threonine	Thr
Asparagine	Asn	Glycine	Gly	Methionine	Met	Tryptophan	Trp
Aspartic acid	Asp	Histidine	His	Phenylalanine	Phe	Tyrosine	Tyr
Cysteine	Cys	Isoleucine	Ile	Proline	Pro	Valine	Val

Peptides and Proteins

What determines the differences in the chemical and physiological properties of peptides and proteins?

A **peptide** is any combination of amino acids in which the amino group of one amino acid is united with the carboxyl group of another amino acid. The amide bond between the carboxyl group of one amino acid and the nitrogen in the amino group of the next amino acid in the peptide chain is called a **peptide bond.** Peptide bonds always involve the central amino and central carboxyl groups. The side chains are not involved in the bonding.

A free amino group is at one end of the peptide. The convention is to write the peptide formula so that the free amino group is at the left end. There is also a free carboxyl group, which appears at the right end of the molecule.

More amino acids may be added to the peptide in the same fashion to form long chains by condensation polymerization. The order in which the amino acids of a peptide molecule are linked is called the amino acid sequence of that molecule. The amino acid sequence of a peptide is conveniently expressed using the three-letter abbreviations for the amino acids. For example, Asp—Glu—Gly represents a peptide containing three amino acids. This tri-peptide contains aspartic acid, glutamic acid, and glycine, in that order, with the free amino group assumed to be on the left end (on the Asp) and the free carboxyl group on the right end (on the Gly). Note that Asp—Glu—Gly is a different peptide from Gly—Glu—Asp because the order of amino acids is reversed, and thus the free amino group and free carboxyl group are on different amino acids.

In theory, the process of adding amino acids to a peptide chain can continue indefinitely. A peptide with more than ten amino acids is a polypeptide. A peptide with more than about 100 amino acids is a **protein.** On average, a molecule of 100 amino acids has a molecular mass of about 10,000 amu. Proteins are an important class of biomolecules. For example, your skin, hair, nails, and muscles are all made of proteins. Proteins are needed for almost all chemical reactions that occur in the body. We can make some of the amino acids that our cells use to make proteins. Other amino acids must be obtained by eating foods rich in proteins, such as the beans in Figure 24.7.

Figure 24.7
Amino Acids in Your Diet
Beans and brown rice are good sources of amino acids.

Differentiated Instruction

L1 STRUGGLING STUDENTS Many laundry detergents contain enzymes that are supposed to help remove stains. Ask students to read the labels of a number of laundry detergents and find out if enzymes are listed among the ingredients. Ask students to hypothesize how enzymes improve the cleaning performance of a detergent.

LPR LESS PROFICIENT READERS Help students create a flowchart to show the steps involved in the binding and subsequent activity of an enzyme.

L3 ADVANCED STUDENTS Have students determine how the amino acid sequence of a protein dictates its secondary and tertiary structure. Ask them to draw a simple protein (or part of one) to show how some of the bonds affect its shape.

Foundations for Reading

BUILD VOCABULARY Have students use a Venn diagram to compare peptides to proteins. They should include the vocabulary for the lesson and ask themselves a series of thought questions, such as, *What do peptides and proteins have in common? What is unique to each?*

READING STRATEGY Have students skim the lesson, paying particular attention to the tables and figures. Have students take notice of the arrangements of peptide molecules: straight chains, helical chains, and pleated sheets.

Explain

Amino Acids

START A CONVERSATION Discuss how to calculate the number of possible arrangements of amino acids in proteins. **Ask** How many different ways can 8 different amino acids be arranged to form a peptide? *(8! = 8 × 7 × 6 × 5 × 4 × 3 × 2 × 1 = 40,320)* **Ask** How many arrangements are possible for a peptide made of 10 different amino acids? *(10! = 3,628,800)* Point out to students that an average protein usually contains more than 100 amino acids.

Explore

Peptides and Proteins

Teacher Demo

PURPOSE Students will observe how amino acids link through amide bonds to form peptides.

PROCEDURE Create models of peptides by linking amino acids with amide bonds. Point out that peptide formation is another example of a condensation polymerization. Ask students to describe how continuing the polymerization process produces protein molecules.

EXPECTED OUTCOME Students should be able to describe peptide formation by manipulating the models.

Explain

Peptides and Proteins

USE VISUALS Point out that the types of amino acids in proteins have a large influence on the physical and chemical properties of a protein. The amino acids listed in Table 24.1 can be grouped into two major categories: polar and nonpolar. Explain that the ratio of polar to nonpolar amino acids profoundly affects the shape of a protein, as shown in Figure 24.8. Convey that when a protein folds, nonpolar amino acids are sequestered to the interior of the protein, away from the aqueous environment, and polar amino acid residues often predominate on the surface of the protein.

CHEMISTRY & YOU Our cells use amino acids to make proteins. Proteins are needed for almost all chemical reactions that occur in the body. One type of protein, known as myoglobin, stores oxygen in muscle cells.

Explore

Teacher Demo

PURPOSE Students will learn that some proteins play structural roles in hard tissue.

MATERIALS thighbone from cooked poultry, 1*M* HCl, beaker

PROCEDURE Students may be surprised to learn that protein is a major structural constituent of bone. Illustrate this fact by soaking a thighbone from cooked poultry in 1*M* HCl overnight. The next day, rinse the bone with water.

EXPECTED OUTCOME Upon visual inspection it may seem as if no reaction has occurred at all, but demonstrate that now the bone can be bent and twisted quite easily. Point out that the mineral salts of the bone were dissolved in the acid. The acid-insoluble portion remaining consists of a special protein called collagen. **Ask** What possible roles does collagen have in the formation and maintenance of healthy bone tissue? *(It provides a framework for the deposition of calcium phosphate, the mineral that makes up bone, and for the growth of bone marrow cells.)*

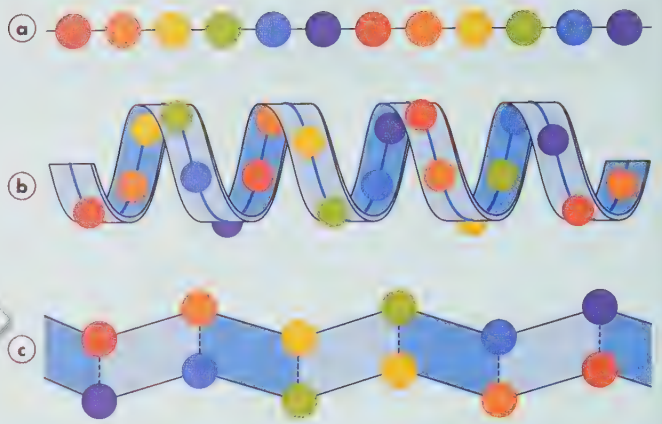


Figure 24.8 Peptide Structures Peptides form three-dimensional shapes. **a.** This is a representation of amino acids in a peptide chain. **b.** The chain may coil into a helix. **c.** Two peptide chains may become arranged in a pleated, sheetlike structure.

Apply Concepts *What types of bonds determine the three-dimensional shape of a protein?*

See protein folding animated online.

CHEMISTRY & YOU

Q: *Why do your muscles need amino acids?*

Differences in the chemical and physiological properties of peptides and proteins result from differences in the amino acid sequence. Twenty amino acids can be linked in an enormous number of ways in a protein molecule. As many as 20^{100} different amino acid sequences are possible for a protein of 100 amino acids containing a combination of the 20 different amino acids.

Protein molecules are folded into relatively stable three-dimensional shapes. Figure 24.8a represents a long peptide chain of a protein, and Figure 24.8b shows how sections of peptide chain may coil into a regular spiral, known as a helix. Peptide chains may also be arranged side by side to form a pleated sheet, as shown in Figure 24.8c. Irregular folding of the chains also can occur. The three-dimensional shape of a protein is determined by interactions among the amino acids in its peptide chains. Protein shape is partly maintained by hydrogen bonds between adjacent folded chains. Covalent bonds also form between sulfur atoms of cysteine side chains that are folded near each other. In that way, separate polypeptide chains may be joined into a single protein. Figure 24.9 traces the shape of myoglobin, a protein that stores oxygen in muscle cells. The peptide chains of most of the myoglobin molecule are twisted into helixes.

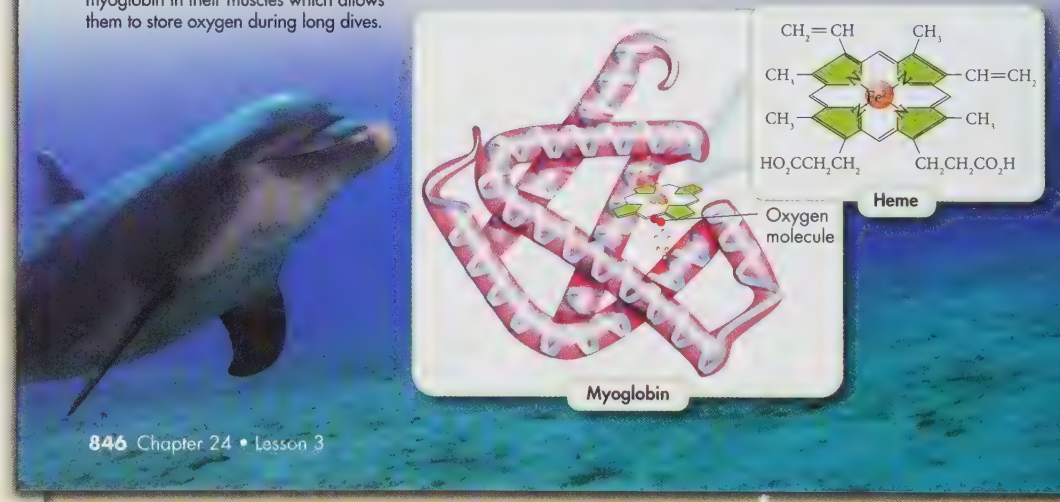

Figure 24.9 Myoglobin The three-dimensional structure of myoglobin, the oxygen storage protein of muscle tissue, is shown here. Most of the peptide chain of myoglobin is wound into helixes. Myoglobin also contains a nonprotein structure called heme. Heme contains four linked rings with an iron(II) ion (Fe^{2+}) at the center. Molecular oxygen binds to the heme iron. Marine animals, such as this dolphin, have a large concentration of myoglobin in their muscles which allows them to store oxygen during long dives.

UbD

Check for Understanding

The Essential Question **What are the characteristics of the four main types of biological molecules?**

Assess students' understanding of proteins by asking them to identify the main characteristics of proteins. *(Proteins are made of chains of over 100 amino acids joined by peptide bonds. Hydrogen bonding and covalent bonding between a protein's amino acids determine its three-dimensional structure.)*

ADJUST INSTRUCTION If students are having trouble answering, have them reread the text of the Peptides and Proteins section and re-examine Figure 24.8.

Enzymes

How do enzymes affect the rates of reactions in living things?

Enzymes are proteins that act as biological catalysts. **Enzymes increase the rates of chemical reactions in living things.** In 1926, the American chemist James B. Sumner reported the first isolation and crystallization of an enzyme. The enzyme he isolated was urease. Urease hydrolyzes urea, a constituent of urine, into ammonia and carbon dioxide. The strong ammonia smell of wet diapers that sit for a long time is the result of the action of bacteria that contain this enzyme. The equation for the reaction is shown below.

$$\underset{\text{Urea}}{H_2N-\overset{\overset{O}{\|}}{C}-NH_2(aq)} + \underset{\text{Water}}{H_2O(l)} \xrightarrow{\text{urease}} \underset{\text{Ammonia}}{2NH_3(g)} + \underset{\text{Carbon dioxide}}{CO_2(g)}$$

Since the discovery of urease, thousands of enzymes have been isolated and structurally characterized as proteins.

In addition to being able to promote reactions, enzymes have two other properties of true catalysts. First, they are unchanged by the reaction they catalyze. Second, they do not change the normal equilibrium position of a chemical system. The same amount of product is eventually formed whether or not an enzyme is present. Few reactions in cells ever reach equilibrium, however. The products tend to convert rapidly to another substance in a subsequent enzyme-catalyzed reaction. According to Le Châtelier's principle, such removal of a product pulls the reaction toward completion.

How Enzymes Work Enzymes catalyze most of the chemical changes that occur in the cell. **Substrates** are the molecules on which an enzyme acts. In a typical enzymatic reaction, shown in Figure 24.10, the substrate interacts with side chains of the amino acids on the enzyme. These interactions cause the making and breaking of bonds. A substrate molecule must make contact with, and bind to, an enzyme molecule before the substrate can be transformed into product. The place on an enzyme where a substrate binds is called the **active site.** An active site is usually a pocket or crevice formed by folds in the peptide chains of the enzyme protein. The peptide chain of an enzyme is folded in a unique way to accommodate the substrate at the active site.

Figure 24.10 Enzyme and Substrate A substrate fits into a distinctively shaped active site on an enzyme. Bond-breaking occurs at the active site to produce the products of the reaction.
Predict ***What would happen if access to the active site were blocked by another molecule?***

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the Small-Scale Lab on page 849. Make sure each group has ELLs of varied language proficiencies so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Provide students with a chart they can use to record the measurements and complete the calculations.

INTERMEDIATE: LOW/HIGH Model the calculations for students with a different-sized egg.

ADVANCED: LOW/HIGH Have students assist less proficient students with the calculations and answering the questions.

Explain

Enzymes

USE VISUALS Have students examine Figure 24.10. Compare the binding of a substrate and an enzyme to the way in which a key fits into a lock. **Ask** How does the enzyme exclude all but the correct substrate? *(The substrate has a matching, or complementary, shape.)* **Ask** What would happen to the system if you heated it until the enzyme shape changed? *(The substrate would no longer fit.)*

Extend

Ask for a show of hands of students who have seen the warning on gelatin packages regarding the use of fresh pineapple or papaya as add-ins. Explain that gelatin is derived from collagen, a connective protein in the skin and bones of animals. Tell students that pineapple and papaya contain enzymes that break down proteins, preventing the gelatin from setting. Challenge students to identify the protein-digesting enzyme in each fruit and to discover why it is safe to use the canned forms of the fruits in a gelatin mold, even though the fresh fruits cannot be used. *(The enzyme in papaya is papain, and the one in pineapple is bromelain. Even though these enzymes are active in fresh fruit, the high temperature used during the canning process inactivates them. Thus, a gelatin mold made with canned papaya or pineapple will set normally.)*

Answers

FIGURE 24.8 hydrogen bonds

FIGURE 24.10 Transformation of the substrate into product could not occur.

Connect to NUTRITION

Explain that coenzymes are often vitamins; for example, B vitamins help release energy from foods. Lack of B vitamins usually produces malnourishment of some kind, since food can't be digested properly without them. Have students determine what occurs if a person is deficient in niacin and vitamin B_6. *(It can produce skin and nervous system disorders, such as headaches, depression, and memory loss.)*

Evaluate

Informal Assessment

Have students form into groups of four. Distribute a sketch of the general structure of a tripeptide, such as Gly—Val—Trp, using letter abbreviations in place of the R group. Ask students to label the peptide bonds and the carboxyl and amino ends. **Ask** Which element do proteins contain that carbohydrates do not? *(nitrogen)* **Ask** What is an enzyme? *(Enzymes are proteins that function as biological catalysts.)* Have students describe one enzyme and its function. *(Sample answer: urease, which catalyzes the hydrolysis of urea)* Then have students complete the 24.3 Lesson Check.

Reteach

Review secondary and tertiary protein structure. Point out that many of the amino acids in an enzyme are not directly involved in catalysis because they lie far from the active site. However, they do participate in intermolecular forces, which maintain the folded shape of the protein. This shape is a prerequisite for its biological activity.

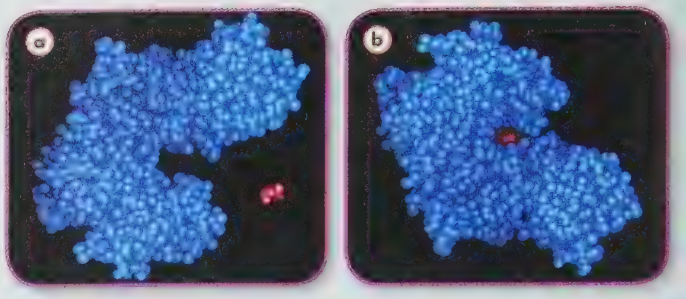

Figure 24.11 Carbonic Anhydrase
a. Carbonic anhydrase (blue) has only one substrate, carbonic acid (red). **b.** An enzyme-substrate complex of carbonic anhydrase and carbonic acid. Notice how the substrate fits snugly into the active site.

Since the active site of each enzyme has a distinctive shape, only a specific substrate molecule can fit into the enzyme, similar to how only one key shape will fit into a certain lock. Thus, each enzyme can catalyze only one chemical reaction at a time. An enzyme-substrate complex is formed when an enzyme molecule and a substrate molecule are joined. Figure 24.11 shows a model of the enzyme-substrate complex formed between the enzyme carbonic anhydrase and its substrate, carbonic acid.

To see the efficiency of enzymes, consider the effects of carbonic anhydrase on carbonic acid. Carbonic anhydrase catalyzes the reversible breakdown of carbonic acid to carbon dioxide and water. One molecule of carbonic anhydrase can catalyze the breakdown of 36 million molecules of carbonic acid in one minute!

$$\underset{\text{Carbonic acid}}{H_2CO_3(aq)} \overset{\text{carbonic anhydrase}}{\rightleftharpoons} \underset{\text{Carbon dioxide}}{CO_2(g)} + \underset{\text{Water}}{H_2O(l)}$$

Figure 24.12 Catalase
Liver contains high levels of the enzyme catalase. When a small amount of crushed liver cells is added to a solution of hydrogen peroxide, oxygen gas is rapidly evolved.

Coenzymes Some enzymes can directly catalyze the transformation of biological substrates without assistance from other substances. Other enzymes need nonprotein coenzymes, also called cofactors, to assist the transformation. Coenzymes are metal ions or small organic molecules that must be present for an enzyme-catalyzed reaction to occur. Many water-soluble vitamins, such as B vitamins, are coenzymes. Metal ions that act as coenzymes include the cations of magnesium, potassium, iron, and zinc. The enzyme catalase includes an iron(III) ion in its structure. Catalase catalyzes the breakdown of hydrogen peroxide to water and oxygen, as shown in Figure 24.12 and in the reaction below.

$$2H_2O_2(aq) \xrightarrow{\text{catalase}} 2H_2O(l) + O_2(g)$$

24.3 LessonCheck

16. Review What are the four groups that surround the central carbon atom in an amino acid?

17. Identify What determines the differences in the properties of peptides and proteins?

18. Explain How do enzymes affect the reaction rates in living things?

19. Identify Which functional groups are always involved in amide bonds?

20. Explain What is meant by the amino acid sequence of a protein?

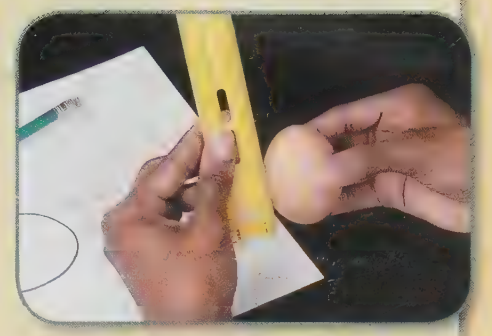
21. Describe Describe three properties of enzymes.

Lesson Check Answers

16. amino, carboxyl, R, and hydrogen

17. differences in the amino acid sequence.

18. Enzymes speed up the rate of reaction but do not affect the position of equilibrium.



19. The amino group of one amino acid combines with the carboxylic acid group of another to form an amide linkage.

20. the order of amino acids in the protein molecule

21. catalysts (they remain unchanged in a reaction); usually proteins; specific to the reactions they catalyze

Small-Scale Lab

The Egg: A Biochemical Storehouse

Purpose

To explore some physical and chemical properties of a chicken egg

Materials

- chicken egg
- ruler
- balance

Procedure

Obtain a chicken egg. Examine the egg's shape, and measure its length and width in centimeters. Measure the mass of the egg. Make an accurate, life-size sketch of your egg and record all of your data on the sketch.

Analyze and Conclude

Using your experimental data, record the answers to the following questions below your drawing.

1. Calculate One way to compare the shapes of eggs is by using a shape index. The shape index is the width (w) of an egg expressed as a percentage of its length (l). Calculate the shape index of your egg.

$$\text{Shape index} = \frac{w}{l} \times 100\%$$

2. Calculate The volume, original mass (when freshly laid), and surface area of an egg can easily be estimated by using the following equations.

$V = (0.5236)(lw^2)$ $m = (0.5632)(lw^2)$

$A = (3.138)(lw^2)^{2/3}$

V = volume m = original mass

A = surface area

Use your data to calculate the volume, original mass, and surface area of your egg. Show your work, and record your results.

3. Compare Which is greater, the measured mass or the calculated mass of your egg? Suggest why the mass of an egg might change over time.

4. Compare Using your measured mass and your calculated volume, calculate the density of your egg. Compare this value with the density of a freshly laid egg (density of freshly laid egg = 1.075 g/cm^3).

You're the Chemist

The following small-scale activities allow you to develop your own procedures and analyze the results.

1. Design an Experiment Design an experiment to answer the following question: Does the mass of an egg change over time?

2. Analyze Data Using your measured mass, your calculated original mass, and your experiments on the mass loss of an egg over time, estimate the age of your egg. What assumptions must you make?

3. Design an Experiment Design and carry out an experiment to measure the volume of your egg. Write down what you did and what you found.

4. Design an Experiment Carry out a series of experiments, or consult with your classmates and use their data, to determine if and how the shape index varies with the size of the egg (small, medium, large, extra large, jumbo).

5. Analyze Data Determine how the mass of an egg varies with its size (small, medium, large, extra large, jumbo).

6. Analyze Data An eggshell contains a calcium carbonate matrix with a protein cuticle. Place one drop of HCl on an eggshell and observe what happens. Write a chemical equation for this reaction. CAUTION *HCl is caustic and can burn skin.*

7. Analyze Data Proteins can be detected by adding aqueous solutions of copper(II) sulfate and sodium hydroxide to a sample. A violet color indicates the presence of protein. Test powdered milk and an eggshell for protein. What are your results?

8. Design an Experiment Design and carry out an experiment to answer the following question: Does temperature affect the mass of an egg over time?

5. Extra-large eggs are usually more than 70 g, and medium eggs are less than 50 g.
6. $2HCl + CaCO_3 \rightarrow CO_2\,(g) + H_2O + CaCl_2$
7. Both powdered milk and the eggshell produce a violet color.
8. Measure the mass of a refrigerated egg for three days. Measure its mass for three more days while storing it at room temperature. The warmer the temperature, the greater the mass loss.

* The original mass of an egg is estimated by multiplying the density of a freshly laid egg, 1.075 g/cm^3 by the equation for the volume of the egg. As a result, the units for mass simply to grams.

Explore

Small-Scale Lab

OBJECTIVE Students examine the physical and chemical properties of a chicken egg.

SKILLS FOCUS Measuring, calculating, designing experiments

PREP TIME 20 minutes

CLASS TIME 20 minutes

MATERIALS Chicken egg, metric ruler, mass balance, NaOH, $CuSO_4$, HCl

ADVANCE PREPARATION Make up reagents as follows:

Solution	Preparation
0.5*M* NaOH	20.0 g in 1.0 L
0.2*M* $CuSO_4$	12.5 g $CuSO_4 \cdot 5H_2O$ in 250 mL
1.0*M* HCl	82 mL of 12*M* in 1.0 L

SAFETY Always add acid to water carefully and slowly!

TEACHING TIPS For each class, obtain at least a dozen eggs of two or three different sizes: medium, large, and extra large. Some markets also sell small or jumbo eggs. Students can then obtain data from classmates about eggs that are different in size from their own. Have students write their names on their eggs so they can identify them the next day. Store some eggs in a refrigerator and some at room temperature if students are going to do activities 1, 2, and 8 in the You're the Chemist section.

EXPECTED OUTCOME Sample data: length 5.90 cm; width 4.55 cm; mass 62.42 g

ANALYZE AND CONCLUDE

1. $\text{Shape index} = \frac{4.55\text{ cm}}{5.90\text{ cm}} \times 100 = 77.1\%$
2. $V = (0.5236)(5.90\text{ cm})(4.55\text{ cm})^2 = 64.0\text{ cm}^3$
   $m = (0.5632)(5.90\text{ cm})(4.55\text{ cm})^2 = 68.8\text{ g}^*$
   $A = 3.138[(5.90\text{ cm})(4.55\text{ cm})^2]^{2/3} = 77.3\text{ cm}^2$
3. The measured mass of 62.42 g is less than the calculated mass of 68.8 g by 6.4 g. The egg may have lost water.
4. $d = \frac{62.42\text{ g}}{64.0\text{ cm}^3} = 0.975\text{ g/cm}^3$
   This is less than the density of a freshly laid egg.

YOU'RE THE CHEMIST

1. Measure the mass each day for two or three days. Eggs lose 0.2 to 0.5 gram per day.
2. Assuming the egg loses 0.20 g per day, the age of the egg is:
   $(68.8\text{ g} - 62.42\text{ g}) \times \frac{1\text{ day}}{0.20\text{ g}} = 32\text{ days old}$
3. Measure the volume by water displacement.
4. Larger eggs have smaller shape indexes.

LESSON 24.4

Key Objective

24.4.1 IDENTIFY the physical property that distinguishes lipids from other biological molecules.

Additional Resources

- Reading and Study Workbook, Lesson 24.4

PearsonChem.com

Engage

CHEMISTRY & YOU Direct students to read the text that begins the lesson. As a class, brainstorm places in the body where fats are found.

Build Background

Display familiar food items such as a tub of margarine, a bottle of olive oil, a stick of butter. Ask students to predict which of these items are fats and which are oils. Students will have an opportunity later to discover the difference between the two.

Foundations for Reading

BUILD VOCABULARY Have students dissect the words *hydrophilic* and *hydrophobic*. Ask them for examples of words that use the same roots, to help distinguish between the meanings.

READING STRATEGY Have students look ahead through the lesson and predict what the properties of lipids are and what types exist. They should check their predictions after they read the lesson. Have students summarize how lipids are different from carbohydrates and proteins.

24.4 Lipids

CHEMISTRY & YOU

Q: *Why is fat an important part of our diet?* The media often portray fat as something that should be avoided because it is bad for you. It is probably not surprising that red meat can be high in fat. But you might not expect avocadoes like the one shown here to be high in fat. In this lesson, you will learn why fats are actually necessary in our diet.

Key Question

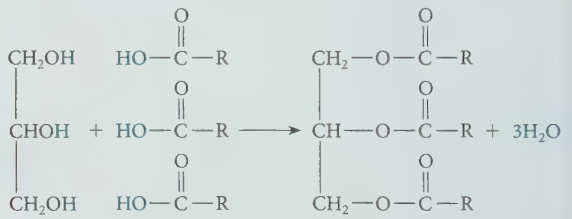
What physical property distinguishes lipids from other classes of biological molecules?

Vocabulary

- lipids
- triglyceride
- saponification
- phospholipid
- wax

Figure 24.13 Fats in Foods Moderate levels of dietary fats and oils are essential to health.

Describing Lipids



What physical property distinguishes lipids from other classes of biological molecules?

Fats, oils, and other water-insoluble compounds are called **lipids.**

Carbohydrates and proteins tend to dissolve in water. Whereas, lipids tend to dissolve readily in organic solvents, such as ether and chloroform. Most fats, such as the butter in Figure 24.13, are obtained from animals. The fats from palm kernels and coconuts, however, are exceptions. Most oils, such as olive oil, are plant products.

Although excessive dietary fat is harmful, you do need some lipids in your diet to stay healthy. Experts recommend that your lipid intake make up less than 30 percent of your daily caloric intake of food. Lipids provide an efficient way for your body to store energy. They are also needed to keep your cell membranes healthy.

Triglycerides Natural fats and oils exist as triesters of glycerol with fatty acids, which are long-chain carboxylic acids (C_{12} through C_{24}). This form of lipid is known as a **triglyceride.** Triglycerides are important as the long-term storage form of energy in the human body. The following equation shows the general reaction for the formation of triglycerides.

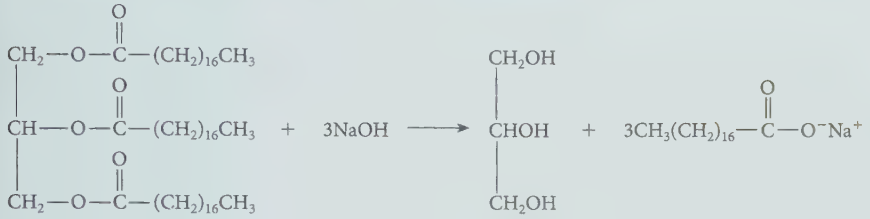
Focus on ELL

1 CONTENT AND LANGUAGE Provide students with a compare/contrast table to organize the information they encounter about the three classes of lipids. If possible, pair beginning and advanced speakers of the same language and allow them to brainstorm in their native language as they work together on their tables.

2 FRONTLOAD THE LESSON Display a bottle of olive oil, a tube of wax lip balm, and a diagram of a cell membrane for students to examine. Explain to them that even though the olive oil, the lip balm, and the cell membrane seem completely unrelated, they all contain lipids. List the three types of lipids on the board, and have students predict which item contains which type of lipid. Have students revisit their predictions after completing the lesson.

3 COMPREHENSIBLE INPUT Explain Figure 24.16 and restate information in its caption as needed. Read the question out loud, and draw a picture on the board that assists students in answering the question.

A fat, such as beef tallow or coconut oil, is mixed with an excess of sodium hydroxide and heated.



Sodium chloride is added to the saponification mixture. This causes the sodium salts of the fatty acids to separate as a thick curd of crude soap.

The crude soap is purified and can then be processed as desired.

Figure 24.14 Soapmaking
These photographs illustrate soapmaking. Once the soap is formed, it is poured into molds. Later it may be milled, or shredded, with scent or color added, and then remolded to produce a finished product.

Like other esters, fats and oils are easily hydrolyzed in the presence of acids and bases. The hydrolysis of oils or fats by boiling with an aqueous solution of an alkali-metal hydroxide is called **saponification.** Saponification is used to make soap. Soaps are thus the alkali metal (Na, K, or Li) salts of fatty acids. A typical saponification reaction is shown below.

As shown in Figure 24.14, soap can be made from a fat, such as beef tallow or coconut oil. Glycerol is an important byproduct of saponification reactions. It is recovered by evaporating the water layer.

Phospholipids Lipids that contain phosphate groups are called **phospholipids.** Phospholipids are abundant in cells. Figure 24.15 shows a typical phospholipid molecule, lecithin. The lecithin molecule has a hydrophilic (water-loving) ionic head and oily or hydrophobic (water-hating) hydrocarbon tails. Recall the solubility rule, "Like dissolves like." Lecithin, which is partly hydrophobic and partly hydrophilic, behaves in water like both an insoluble hydrocarbon and a soluble ionic compound. In water, the hydrophobic carbon chains of lecithin aggregate to exclude water. The hydrophilic part is drawn to water, which can solvate it. In water, phospholipids spontaneously form a spherical double layer, called a lipid bilayer, in which the hydrophobic tails of phospholipid molecules are sandwiched between two layers of hydrophilic heads.

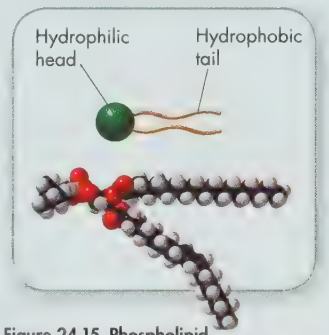


Figure 24.15 Phospholipid
In the simplified diagram, the hydrophilic head is shown as a sphere and the hydrophobic tails as wavy lines. The space-filling model is the phospholipid lecithin.

Differentiated Instruction

L1 SPECIAL NEEDS Create a model of a cell membrane by floating a layer of table-tennis balls in a tub of water. Add a few tennis balls. Explain that the water underneath the balls represents the cytoplasm of the cell, the table-tennis balls represent the phospholipids, and the tennis balls represent the proteins.

LPR LESS PROFICIENT READERS Write the words *triglyceride* and *saponification* on the board, along with pronunciation guides for them. Have students practice pronouncing the words, and have them write the pronunciation guides in their notebooks.

L3 ADVANCED STUDENTS Have students determine the structure of oleic acid, noting the hydrophobic region and the hydrophilic region.

Explain

Describing Lipids

START A CONVERSATION Explain that lipids contain identifiable functional groups, but their most distinguishing property is their insolubility in water. **Ask** Why do you think lipids are insoluble? *(They are nonpolar.)* **Ask** What utility does this characteristic give lipids? *(They can be used to contain water-soluble products and processes.)*

Explore

Student Activity

Have students compare the composition of butter, regular margarine, and low-calorie margarine by melting the same mass of each kind of spread in separate test tubes. Put the test tubes in warm water to liquefy the samples. Then allow the samples to settle. The liquid will form two layers: the top layer is a lipid (butterfat or partially hydrogenated vegetable oil) and the bottom layer is water. Students can compare the samples quantitatively and qualitatively and calculate the percentage of water in each fat.

MAKE A CONNECTION Explain to the class that lipid bilayers are an important component of cells today and were probably essential to the origin of cellular life. Convey that before DNA and RNA existed to direct the formation of complex molecules, molecules had to be able to self-assemble. Point out that bipolar molecules like phospholipids can assemble themselves into membranes; a membrane-bound environment was an important step in providing a place for complex biological chemistry.

Explain

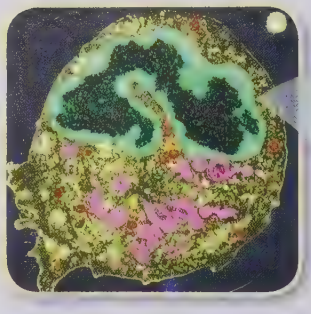
Describing Lipids

USE VISUALS Have students study Figure 24.15. **Ask** Why are the phospholipid tails facing each other? *(They are hydrophobic and the membrane is surrounded by water.)*

Waxes

APPLY CONCEPTS Point out that an important difference between waxes and oils is the length of the hydrocarbon backbone. Explain that waxes are derivatives of high molar mass carboxylic acids. Remind students that carboxylic acids react with alcohols to form esters. Thus, waxes are essentially high molar mass esterification products of carboxylic acids.

CHEMISTRY & YOU Fats provide an efficient way for your body to store energy. They are also needed to keep your cell membranes healthy.



Evaluate

Informal Assessment

Display samples of different types of lipids and ask students to decide what type each is, why they think so, and what that implies about the structure of the lipid. Then have students complete the 24.4 Lesson Check.

Reteach

Review the chemical structures on pages 850 and 851. Help students to understand that the fats and oils hydrolyze in the presence of acids or bases because lipids are esters.

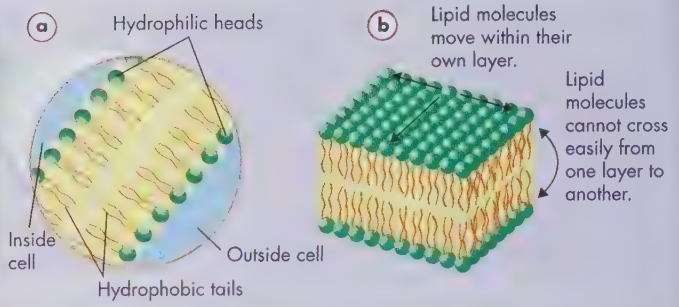


Figure 24.16 Lipid Bilayer
A cell membrane has a lipid bilayer structure. **a.** The hydrophilic heads are in contact with water, but the hydrophobic tails are not. **b.** The lipid molecules move easily within their own layer but do not readily move to the other layer.
Apply Concepts ***What prevents a lipid molecule from crossing to the opposite side of the bilayer?***

Cell membranes, such as the one shown in Figure 24.16, consist primarily of lipid bilayers. The lipid bilayer of a cell membrane acts as a barrier against the passage of molecules and ions into and out of the cell. However, cells do need to take in certain ions and molecules, such as nutrients, while excluding other materials. Selective absorption is accomplished by the protrusion of protein molecules through the lipid bilayer. These proteins form channels through which specific ions and molecules can selectively pass. Not all membrane proteins extend all the way through the membrane. Proteins, such as enzymes, may be bound to the interior surface of the membrane. Many membrane proteins have attached carbohydrate molecules. The carbohydrate portion is on the exterior of the lipid bilayer, where it can hydrogen-bond with water. The protein portion is on the interior of the lipid bilayer, so it does not contact the water.

CHEMISTRY & YOU

Q: *Why is fat an important part of our diet?*

Waxes Another type of lipids are **waxes.** Waxes are esters of long-chain fatty acids and long-chain alcohols. The hydrocarbon chains for both the acid and the alcohol usually contain from 10 to 30 carbon atoms. Waxes are low-melting, stable solids. In many plants, a wax coat protects the surfaces of leaves from water loss and attack by microorganisms. For example, carnauba wax, a major ingredient in car wax and floor polish, is found on the leaves of a South American palm tree. In animals, waxes coat the skin, hair, and feathers and help keep these structures pliable and waterproof.

24.4 LessonCheck

22. Compare What physical property sets lipids apart from biological substances such as carbohydrates and proteins?

23. Compare Compare the molecular structures of the three main types of lipids.

24. Identify What are the products of a saponification reaction?

25. Explain What role do phospholipids and proteins play in cell membranes?

26. Explain How do phospholipids behave in water?

27. Identify What two classes of organic compounds combine to form a wax?

28. Identify What is the function of waxes in plants? In animals?

Lesson Check Answers

22. Lipids do not dissolve in highly polar solvents such as water.

23. Triglycerides are triesters of glycerol with long chains of fatty acids attached. Phospholipids are lipids that contain phosphate groups; they have a hydrophobic end and a hydrophilic end. Waxes are esters of long-chain fatty acids and long-chain alcohols.

24. glycerol and a soap

25. Phospholipids make up the lipid bilayer of the cell membrane. Protein molecules protrude from this layer, forming channels through which nutrients pass.

26. They spontaneously form a lipid bilayer, with hydrophobic tails of the phospholipids in the middle.

27. long-chain fatty acids and long-chain alcohols

28. Wax protects the surfaces of leaves from water loss and attack by microorganisms. Wax keeps skin, hair, and feathers pliable and waterproof.

Biochemists

Biochemistry is the chemistry of life, and biochemists combine the fields of chemistry, microbiology, cell biology, genetics, and physics to study the chemical and physical processes of cells and organisms.

Biochemists often work in medical, agricultural, and food-related fields. Those working in medical fields may investigate the causes of diseases and genetic disorders and develop new drugs and medications. They might also research the chemical changes that take place in cells to identify how substances such as drugs, hormones, and household chemicals affect cells, tissues, and body functions. Biochemists working in agriculture may develop new techniques for such tasks as crop cultivation and pest control. Biochemists working in food science may analyze the effects of cooking, canning, and processing on the nutritional value of foods, or they may study the effects of certain foods and nutrients on the human body.

FLU FIGHTERS Biochemists investigate the chemical aspects of the immune system and viruses to create vaccines that help prevent viral diseases such as known strands of influenza viruses.

CREATING BIOFUELS Understanding both plant genetics and chemistry allows biochemists to research how plants such as corn and soy can be used as renewable fuel sources.

MONITORING THE ENVIRONMENT Biochemists analyze the effects of environmental conditions on plants and animals such as these corals in the Indian Ocean.

Take It Further

1. Identify What are three life processes that depend on chemistry? Explain your answer.

2. Evaluate the Impact on Society What is one way in which understanding the chemical processes involved in aging might help future generations?

Differentiated Instruction

L1 STRUGGLING STUDENTS Read aloud the description of Flu Fighters, and have students examine the photo. Lead students in discussing why this job is important, and then have them write a sentence describing the job. Repeat this process for Monitoring the Environment and Creating Biofuels. Discuss how learning about different careers can help students plan their futures.

ELL ENGLISH LANGUAGE LEARNERS Have students skim through the passages to find unfamiliar words before reading the text. For each of the three jobs represented in the photos, have students write a sentence about how working in one of these jobs in their native country would benefit that country. Allow time for students to share this information with the class.

L3 ADVANCED STUDENTS Have students conduct online research about the educational requirements for a career in biochemistry. Tell students to take on the role of a recruiter. Instruct them to create a technological presentation that persuades students to pursue the study of biochemistry after graduation from high school.

CHEMISTRY & YOU Draw students' attention to the photo labeled *Flu Fighters*. Remind students that a virus particle is basically a packet of DNA or RNA surrounded by a protein coat (a capsid) and possibly an additional outer envelope of lipids and proteins. The surface proteins help virologists classify viruses into one of three main types (A, B, or C). Type A influenzas are divided into subtypes, based on specific combinations of two proteins: hemagglutinin (HA) and neuraminidase (NA). Each protein has several variations. Pose the following question to students: *How would you characterize swine influenza?* You may need to assist students in the following ways:

- The natural hosts of type A influenzas are birds, but these influenzas can be transmitted to humans and other animals, such as horses and pigs.
- Humans are natural hosts of types B and C influenzas.
- Swine influenza is officially designated as H1N1 influenza.
- Type A influenzas are capable of causing deadly epidemics and pandemics, but type B is only associated with epidemics. Type C outbreaks are sporadic and mild.

Explain

APPLY CONCEPTS Point out that there are many fields in which biochemists are needed. Have students name several fields of scientific research or manufacturing. For each field they name, have students consider how a biochemist might be needed. Examples include studying ways to increase plant yields or insect resistance for crops and studying types of nutrients and medicines for farm animals.

Extend

Connect to SPACE SCIENCE

The first female commander of the International Space Station was Peggy Whitson, a biochemist. As part of her responsibilities on the space station, she conducted biochemical research into the effects of low-gravity conditions on plants. Have students find the results of her research and write a report detailing the results and her conclusions.

Answers

FIGURE 24.16 the hydrophobic center of a lipid bilayer

TAKE IT FURTHER

1. Possible answers include aging, reproduction, heredity, and the immune system.
2. Biochemists could develop drugs to treat diseases associated with aging such as Alzheimer's disease.

LESSON 24.5

Key Objectives

- **24.5.1 IDENTIFY** the functions of DNA and RNA.
- **24.5.2 IDENTIFY** the number of bases of DNA required to specify one amino acid in a peptide chain.
- **24.5.3 EXPLAIN** gene mutations.
- **24.5.4 IDENTIFY** two examples of DNA technology used today.

Additional Resources

- Reading and Study Workbook, Lesson 5

PearsonChem.com

Engage

CHEMISTRY & YOU Point out that some physical traits are inherited, while others are acquired during life. **Ask** What are some inherited traits? *(hair color, eye color, blood type)* **Ask** What are some acquired traits? *(muscle mass, hair length, skills)*

Build Background

Have students call out all possible three-letter arrangements of A, B, and C (allow double and triple letters as in AAA, AAB, and so on), and list the arrangements on the board. *(There should be 27 possible arrangements.)* Tell students that the body uses nucleic acids in a similar fashion to code for amino acid sequences in proteins.

IN ACADEMIC STANDARDS for SCIENCE

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.

24.5 Nucleic Acids

CHEMISTRY & YOU

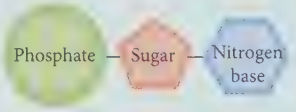
Q: *Why do children often look similar to their parents?* Maybe people have told you that you have your mother's eyes or your father's nose. Although this is not literally true (your eyes and nose are your own), you do inherit some traits from your parents. In this lesson, you will learn about molecules that are involved in the inheritance of traits from parents.

Key Questions

- *What are the functions of DNA and RNA?*
- *How many bases of DNA are required to specify one amino acid in a peptide chain?*
- *What are gene mutations?*
- *What are two examples of DNA technologies used today?*

Vocabulary

- nucleic acid
- nucleotide
- gene



DNA and RNA

What are the functions of DNA and RNA?

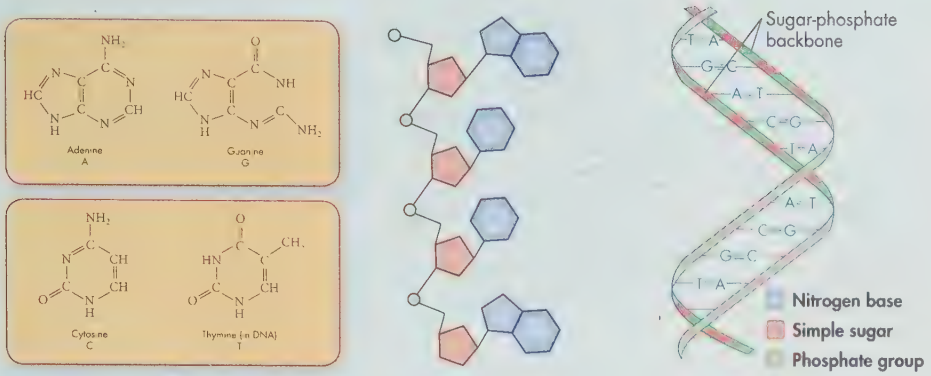
More than 100 years ago, a Swiss biochemist discovered a class of nitrogen-containing compounds in the nuclei of cells. The nuclei were first obtained from dead white blood cells in the pus of infected wounds. The eventual understanding of the biological role of the compounds has led to a revolution in biochemistry.

These nitrogen-containing compounds, called **nucleic acids,** are polymers that are found primarily in a cell's nucleus. They are indispensable components of every living thing. Two kinds of nucleic acids are in cells—*d*eoxyribo*n*ucleic *a*cid (DNA) and *r*ibo*n*ucleic *a*cid (RNA). **DNA stores the information needed to make proteins and governs the reproduction and growth of cells and new organisms. RNA has a key role in the transmission of the information stored in DNA and in the synthesis of proteins.**

The monomers that make up the DNA and RNA polymers are called **nucleotides.** Nucleic acids are therefore polynucleotides. As shown below, each nucleotide consists of a phosphate group, a five-carbon sugar, and a nitrogen-containing unit called a nitrogen base.

Nucleotide

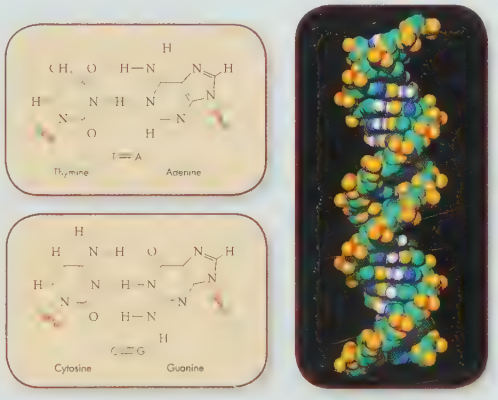
The sugar unit in the nucleotides of DNA is the five-carbon monosaccharide known as deoxyribose. There are four different nitrogen bases in DNA—adenine, guanine, thymine, and cytosine. These four bases are abbreviated A, G, T, and C, respectively, and are shown in a short segment of a DNA molecule in Figure 24.17. Notice that adenine and guanine each contains a double ring and that thymine and cytosine each contains a single ring. Ribose, which has one more oxygen atom than deoxyribose, is the sugar found in the nucleotide monomers of RNA. The base thymine is never found in RNA. Instead, it is replaced by a fifth nitrogen base, called uracil, which is abbreviated U.



Focus on ELL

1 CONTENT AND LANGUAGE Explain what acronyms and abbreviations are and why people use them. Write *ASAP, SCUBA,* and *LASER* on the board and write below each word the meaning of each letter. Then write *DNA* and *RNA* on the board and discuss what the letters stand for.

2 FRONTLOAD THE LESSON As a class discuss the shortcuts students use when texting, instant messaging, or e-mailing, such as *LOL, BRB,* and *BBS*. Then tell students that, just as they use these three-letter codes to convey specific meanings in electronic conversation, DNA uses nucleic acids grouped in threes to code for specific amino acids.



3 COMPREHENSIBLE INPUT Manipulate a physical model of the DNA helix while discussing Figures 24.17 and 24.18. When discussing mutations, repeat the red cat exercise but add a letter to represent an insertion. Repeat again by changing a letter to represent a point mutation.

Figure 24.17 DNA
The nucleotide monomers of DNA are linked together through their sugar-phosphate groups. Two strands of DNA coil into a helix.

Chemists studying nucleic acids discovered that the amount of adenine in DNA always equals the amount of thymine (A = T). Similarly, the amount of guanine always equals the amount of cytosine (G = C). The significance of these facts was not apparent until 1953, when James Watson and Francis Crick proposed that the structure of DNA consists of two polynucleotide chains wrapped into a spiral shape, as in Figure 24.17. This spiral is the famous double helix of DNA. For the nitrogen bases to fit neatly into the double helix, every double-ringed base on one strand must be paired with a single-ringed base on the opposing strand. The pairing of A with T and G with C not only provides the best possible fit; it also allows the maximum number of hydrogen bonds to form between the opposing bases, as Figure 24.18 shows. Thus, the pairing of A and T (with two hydrogen bonds between the opposing bases) and of G and C (with three hydrogen bonds) makes for the most stable arrangement in the double helix.

Figure 24.18
Hydrogen Bonding in DNA
The two DNA strands in a double helix are held together by many hydrogen bonds; there are two hydrogen bonds between each thymine (T) and adenine (A) and three hydrogen bonds between each cytosine (C) and guanine (G).
Interpret Diagrams ***In the pairing of C with G, how many hydrogen bonds involve nitrogen? How many involve oxygen?***

Check for Understanding

The Essential Question **What are the characteristics of the four main types of biological molecules?**

Have students write a brief summary of the characteristics of nucleic acids. *(There are five naturally occurring nucleic acids, each with a phosphate, a sugar, and a nitrogen base. The sugar in RNA is ribose; the sugar in DNA is deoxyribose. The five bases are adenine (A), guanine (G), cytosine (C), thymine (T), and uracil (U). Both RNA and DNA contain adenine, guanine, and cytosine. DNA also contains thymine; RNA contains uracil in place of thymine. The DNA helix is formed from two complementary strands of DNA, in which A bonds with T and C bonds with G.)*

ADJUST INSTRUCTION For the students struggling with this concept, have them reread the section on DNA and RNA, and then review Figures 24.17 and 24.18 with them. If possible, make DNA model kits available for students to manipulate.

Foundations for Reading

BUILD VOCABULARY Explain to students that the root of many key words in this lesson relates to the nucleus of the cell. Point out that nucleic acid, for example, was first found in the nucleus of eukaryotic cells and that nucleotides are the compounds that make up these nucleus-inhabiting acids.

READING STRATEGY Have students identify the main idea under each orange heading. Ask them to note details as they read that support the main idea for that portion of the text.

Explain

DNA and RNA

USE VISUALS Have students examine Figure 24.17. Point out the sequence complementarity between strands. **Ask** How does the experimental data that moles A = moles T, and moles G = moles C support the concept of base pairing? *(A and G are always hydrogen-bonded to T and C, respectively, in the opposite strand. Thus, there is a one-to-one mole correspondence.)*

Then direct students' attention to the molecular structures in Figure 24.18. **Ask** What features of the structure of the bases make this arrangement the best fit? *(two hydrogen bonds in the T-A connection, three for C-G, and length of bonds)*

Answers

FIGURE 24.18 nitrogen, 1; oxygen, 2

Explore

QuickLab

OBJECTIVE Students will construct a model of double-stranded DNA.

SKILLS FOCUS Using models, inferring

PREP TIME 10 minutes

CLASS TIME 20 minutes

MATERIALS Cardboard tube from paper-towel roll; felt-tip markers, two colors; metric ruler; thumbtack; 10 toothpicks

TEACHING TIPS To help students get parallel strands, have them cut a thin strip of paper that just wraps around the tube (following the spiral seam); then they can measure the length of the paper, marking points along it every 5 cm. Students can use the paper to mark points on the tube and connect points to draw the parallel strand.

EXPECTED OUTCOME Models should have an orderly column of bases on the inside, with phosphate and sugar groups on the outside. **Ask** What forces hold the two strands of DNA together? *(Primarily hydrogen bonding; dispersion forces also act between stacked bases.)* **Ask** What forces the two strands apart? *(Repulsion of negative charges on phosphate groups; two strands have greater entropy than a single helical structure.)*

ANALYZE AND CONCLUDE

1. Base pairs are neatly stacked inside the double helix.
2. the exterior
3. the exterior

FOR ENRICHMENT **Ask** What must occur to replicate base pairs of DNA? *(The two strands must separate.)* Instruct students to alter their model so that it can be used to demonstrate DNA replication.

QuickLab

A Model of DNA

Purpose To construct a model of double-stranded DNA

Materials

- cardboard tube from paper-towel roll
- felt-tip markers (two colors)
- metric ruler
- thumbtack
- 10 toothpicks

Procedure

1. The typical cardboard tube has a seam that, when viewed from one end, shows a spiral that moves away from the observer. This spiral is a helix. Outline the spiral seam with a colored marker.
2. Using a different-colored marker, draw a second spiral midway between the lines of the first. These two spirals represent the two strands of double-stranded DNA.
3. Measure along the tube, and mark a dot on each spiral every 5 cm. Label each dot with the letter *S* to indicate a sugar unit. Make a hole in the spirals at each *S* mark with the thumbtack. Move down each spiral and mark a letter *P* to indicate a phosphate group halfway between each of the *S* dots.
4. Color each toothpick along half its length with a marker. A toothpick represents a base pair in the DNA molecule.
5. Starting at the top of the tube, insert a toothpick in one hole at an *S* label and guide it so it emerges through the hole in the *S* on the opposite side of the tube. Repeat the process for the other holes.

Analyze and Conclude

1. **Use Models** Are the bases on the interior or the exterior of the double helix? Are they randomly arranged or neatly stacked?
2. **Analyze Data** Are the phosphate groups on the exterior or the interior of the DNA structure?
3. **Analyze Data** Are the sugar groups on the interior or the exterior of the DNA molecule?

The Genetic Code

How many bases of DNA are required to specify one amino acid in a peptide chain?

An organism contains many proteins that are characteristic of that particular organism. The proteins of earthworms are different from the proteins of pine trees, which are different from the proteins of humans. How do cells in a given kind of organism know which proteins to make? The cells use the instructions contained in the organism's DNA. A **gene** is a segment of DNA that carries the instructions for making one peptide chain. Thus, the products of genes are the peptides and proteins found in an organism.

You can think of DNA as a reference manual that stores the instructions for building proteins. The instructions are written in a simple language that has 4 "letters"—the bases A, T, G, and C. Experimental data show that each "word" in a DNA manual is exactly three letters in length. Each three-letter base sequence, or triplet, codes for one of the 20 common amino acids. The code words are strung together in the DNA molecule to form genes, which specify the order of amino acids in peptides and proteins. **Three bases of DNA arranged in a specific sequence are required to specify one amino acid in a peptide or protein chain.**

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in pairs to complete the lab. Make sure each pair has students of varied language proficiencies so that a proficient student can help a less proficient student. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Model the creation of the double helix by systematically showing students what to do at each step of the procedure. Have students write a description of each step of the procedure in their native language during your demonstration.

INTERMEDIATE: LOW/HIGH For their responses to the Analyze and Conclude questions, allow students to answer orally and to point to places on their models.

ADVANCED: LOW/HIGH Paraphrase the procedure and Analyze and Conclude questions for students with lower English proficiencies. Encourage students to use symbols and diagrams when applicable.

Table 24.2 provides the DNA code words for the 20 common amino acids. For example, you can see that the DNA code word AAA specifies the amino acid phenylalanine (Phe) and that the DNA code word CGA specifies the amino acid alanine (Ala). Note that most amino acids are specified by more than one code word, but a code word never specifies more than one amino acid. With DNA code words of three letters, 900 bases arranged in a specific sequence would be required to code for a peptide chain made up of 300 amino acids arranged in a specific sequence.

One of the the code words (TAC) signifies the initiation of a peptide. Three code words (ATT, ATC, and ACT) are reserved as end, or termination, code words. The translation of a base sequence of DNA in a gene into the amino acid sequence of a peptide begins with the initiation code word and runs continuously until a termination code word is reached. The termination code word signals a stop to the addition of amino acids in the production of the peptide. You can think of a termination code as being similar to the period at the end of a sentence.

The molecular masses of DNA molecules reach into the millions and possibly billions. Even with only four bases, the number of possible sequences of nucleotides in a DNA chain is enormous. The sequence of the nitrogen bases A, T, G, and C in the DNA of an organism constitutes the genetic plan, or blueprint, for that organism. This genetic plan is inherited from parents and passed to offspring. Differences in the number and sequence of the bases in DNA ultimately are responsible for the great diversity of living creatures found on Earth.

CHEMISTRY & YOU

Q: *Why do children often look similar to their parents?*

Table 24.2

Three-Letter DNA Code Words for the Amino Acids

First Letter in Code Word	Second Letter in Code Word: A	G	T	C	Third Letter in Code Word
A	AAA Phe	AGA Ser	ATA Tyr	ACA Cys	A
	AAG Phe	AGG Ser	ATG Tyr	ACG Cys	G
	AAT Leu	AGT Ser	ATT End	ACT End	T
	AAC Leu	AGC Ser	ATC End	ACC Trp	C

	CAC Val	CGC Ala	CTC Glu	CCC Gly	C

Differentiated Instruction

L3 ADVANCED STUDENTS Challenge students to write a computer program that converts any sequence of DNA bases into an amino-acid sequence by using the three-letter codes in Table 24.2.

LPR LESS PROFICIENT READERS Provide students with a copy of Table 24.1 from Lesson 24.3 so they can know what amino acids the abbreviations in Table 24.2 represent. Help students interpret the information present in both tables.

L1 STRUGGLING STUDENTS Review the difference between hydrogen bonding and chemical bonding. Reinforce the concept that DNA strands are held together by hydrogen bonds rather than as a result of chemical reactions.

Explain

The Genetic Code

CHEMISTRY & YOU Proteins determine a variety of traits. DNA contains the instructions for which proteins cells should make. Offspring inherit DNA from their parents.

USE AN ANALOGY Display a copy of the Morse code. Tell students that the millions of possible sequences from the combination of only four nucleotides can be compared to the very large number of words that are formed from only two symbols—the dot and dash of Morse code. Moreover, both systems use patterns to communicate information. Point out, however, that Morse code is a relatively simple human invention that uses arbitrary combinations of dots and dashes to represent letters of the alphabet. The genetic code is a complex natural communication system that directs and controls all life processes. Make clear to students that while Morse code combinations vary from one to five symbols, all the base sequences in the genetic code are exactly three bases in length.

MAKE A CONNECTION Tell students that cracking the genetic code was one of the greatest achievements of modern science. Make sure students understand that the three-letter codes used to translate DNA to protein are the same in humans and in bacteria. Have students ponder this concept and then ask them to state what implications this has for the evolution of life on Earth. *(It supports the argument that life on Earth evolved only once.)*

USE VISUALS Direct students' attention to Table 24.2. **Ask** How many three-letter codes are there? *(64)* **Ask** Are all possible combinations of bases used? *(yes)* **Ask** Why are there more codes than amino acids? *(Some amino acids have more than one code.)* **Ask** Is there an advantage to redundant codes? *(Redundancy might protect against harmful mutations.)*

Explore

Gene Mutations

Class Activity

Have students practice reading the genetic code. Write a number of short DNA sequences on the board and ask students to use Table 24.2 to translate the genetic information into an amino-acid sequence. *(Example: A-C-G-G-C-A-A-G-A-G-A-A-T-G-G-A-C-T Cys-Arg-Ser-Leu-Thr-End)*

Then, ask students to predict the effects of substitutions, additions, and deletions on the translation of the DNA sequence. **Ask** How might this sequence be affected if a thymine were substituted for the first guanine? *(This mutation would insert a stop code. The protein synthesis would prematurely terminate, and there would most likely be no biological activity.)*

Extend

Connect to MEDICINE

Have students research two common gene mutations and two rare gene mutations and the effects of each in humans or animals. Encourage students to determine if the mutations resulted from a substitution, addition, or deletion of one or more nucleotides.

Gene Mutations

What are gene mutations?

When a change occurs in a DNA code word, the result is a mutation in the DNA. **Substitutions, additions, or deletions of one or more nucleotides in the DNA molecule are called gene mutations.** The effect of the deletion of a single base from a gene can be illustrated by the following analogy. Suppose a string of letters of the alphabet goes as follows:

PATTHEREDCAT

The letters may not make sense at first glance. However, if you separate them into three-letter words, they form a perfectly sensible statement:

PAT THE RED CAT

Now delete the first letter, and again separate the string into three-letter segments:

ATT HER EDC AT

This last sequence is nonsensical. Similarly, the deletion of a base in the DNA base sequence can turn the information into nonsense. A sequence that once may have coded for the proper sequence of amino acids in a necessary protein may be replaced by a sequence that produces a useless or damaging amino acid sequence. The same sort of harmful effect may be produced by mutations involving substitutions or additions of nucleotides.

Such mutations might result in the production of a faulty protein or of no protein at all. Diseases that result from gene mutations are called genetic disorders. Thousands of genetic disorders have been identified. Galactosemia is an example of a genetic disorder that affects about 1 in 55,000 newborn babies. Galactosemia results from a mutation in an enzyme called GALT (galactose-1-phosphate uridyl transferase). GALT is needed to break down the sugar galactose into glucose, as shown in Figure 24.19. Without normal GALT, galactose can build up in the body and cause kidney failure, an enlarged liver, cataracts, and brain damage. Newborns are usually tested for galactosemia at birth. The only way to treat galactosemia is to avoid foods that contain galactose, such as milk, cheese, and dried beans.

Not all gene mutations are harmful. Occasionally, a mutation can result in the synthesis of a protein that is more efficient than the version that previously existed. Such a mutation could thus be beneficial to the survival of the affected organism.

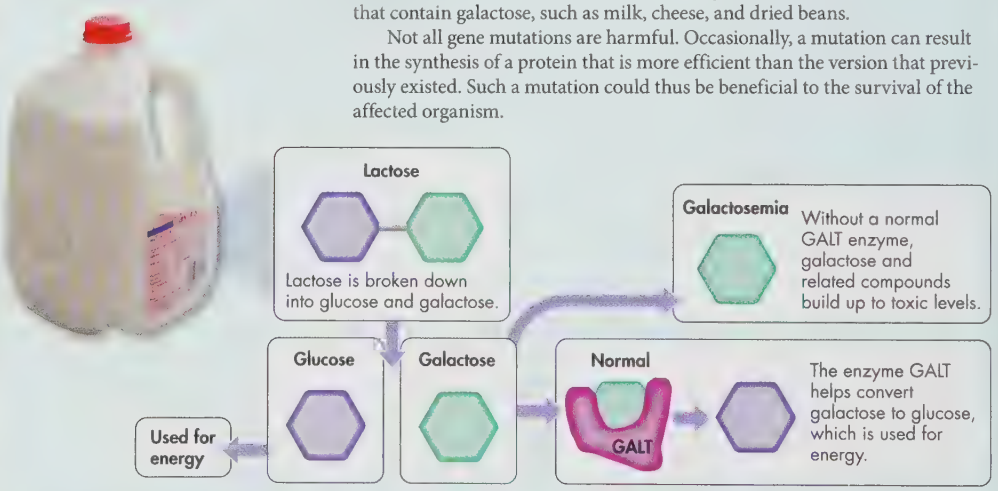

Figure 24.19 Galactosemia
Persons with galactosemia have mutations in the gene for the enzyme GALT. They cannot complete the breakdown of lactose. Any food containing galactose or lactose, including milk and products containing milk, should be avoided.

Professional Development Note

Caffeine Mutations?

Many people have looked for health risks associated with the consumption of caffeinated beverages. One concern raised is the potential mutagenic effects due to the misincorporation of caffeine into nucleic acids. Caffeine is a nitrogen compound that is structurally related to purine bases, especially guanine. Its resemblance may allow it to bind to DNA-synthesizing enzymes, which would incorporate it into a polynucleotide. However, caffeine lacks hydrogen for proper base pairing, and this would destabilize the DNA helix.

DNA Technologies

What are two examples of DNA technologies used today?

Since DNA is such an important part of living things, it may not be surprising that DNA technology has had a significant impact on our society. In the following pages, you will learn about some of these technologies.

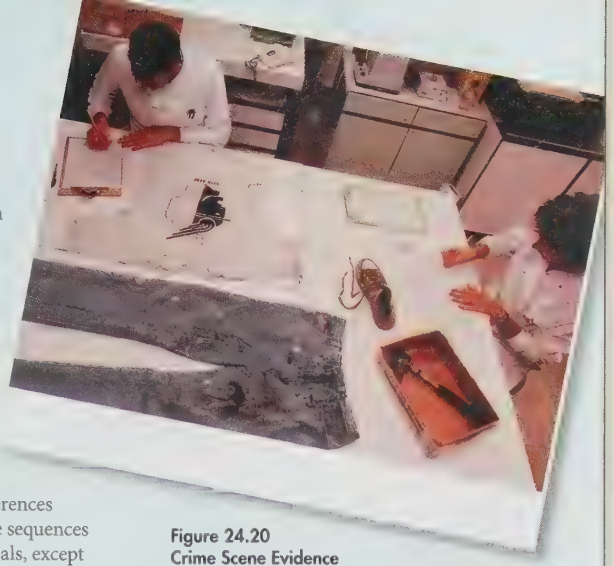

Figure 24.20
Crime Scene Evidence
These scientists are analyzing items taken from a crime scene. DNA may be isolated from blood on the items, in this case clothing and an axe.

DNA Typing Only a small fraction of a human's DNA is used for coding the information needed for protein synthesis. The rest consists of repeating, noncoding base sequences that separate or sometimes interrupt gene coding sequences. The role of these stretches of noncoding DNA is unclear. The noncoding sequences are similar for members of the same family but are slightly different for almost every individual. Differences also exist in the coding portions of DNA. The base sequences of DNA are slightly different for different individuals, except for identical twins. Identical twins look similar because they have identical DNA.

DNA typing uses the variation in the DNA of individuals as a basis for creating DNA profiles to identify a person from samples of his or her hair, skin cells, or body fluid. Because DNA sequences, like fingerprints, are unique for each individual, DNA typing has also been called DNA fingerprinting. To construct a DNA profile, scientists first isolate the DNA in a sample. Only a tiny sample is needed. A sample can be anything that contains DNA, including teeth, fingernails, blood, hair, saliva, and skin cells. Figure 24.20 shows some items that investigators obtained from a crime scene.

Samples can be typed in several different ways, but the method used most commonly by the Federal Bureau of Investigation (FBI) is short tandem repeat (STR) analysis. A short tandem repeat is a short segment of DNA that is repeated several times. For example, one of the regions of DNA used by the FBI contains repeats of the sequence AGAT. To obtain a profile, the FBI looks at 13 different STR regions.

The DNA profile can then be compared with a sample of DNA from a known individual, as Figure 24.21 shows. The FBI has a technology system called the Combined DNA Indexing Systems (CODIS) that allows laboratories throughout the country to share and search DNA profiles. The chances of two people (except for identical twins) having the same DNA profile for these 13 regions is 1 in 1 billion.

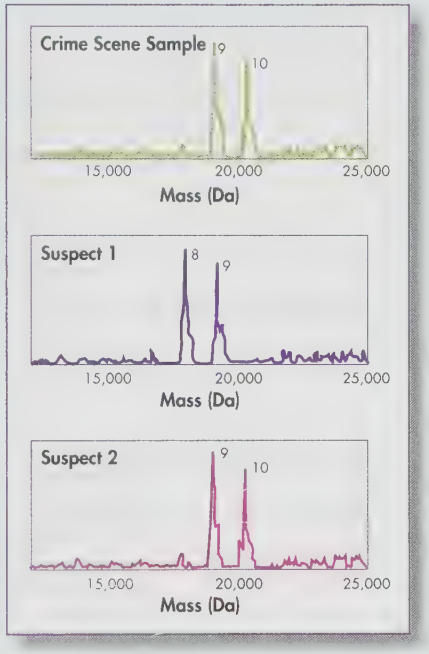

Figure 24.21 DNA Profile
This is an example of what a DNA profile for one STR region might look like. The DNA from the crime scene has a segement with 9 repeats and a segment with 10 repeats. Suspect 1 can be eliminated because the length of that person's segments does not match the crime scene sample.

Differentiated Instruction

L3 ADVANCED STUDENTS Have students research the legal programs started after 1992 when the National Research Council expressed support for DNA testing as a means for identifying criminals. Have students find the statistics showing the number of convictions overturned since the inception of these legal programs.

L1 SPECIAL NEEDS STUDENTS Using an ink pad and a sheet of plain paper, take one fingerprint each from two or three volunteers. Project the fingerprints on a screen. Ask students if they see any fingerprints that are exactly alike. Convey that no two people have the same fingerprint, and then relate this concept to DNA.

ELL ENGLISH LANGUAGE LEARNERS Write the word *profile* on the board. Explain that it has both common and scientific meanings. Assign students to small groups of varying proficiencies, and have each group look up the definitions of this term in a dictionary and identify the definition that most closely fits the context of DNA profiles.

Explain

DNA Technologies

APPLY CONCEPTS Forensic investigators try to understand a crime by using a variety of tactics. They often try to collect evidence that will allow them to create a DNA profile. Analysts then cross-check the profile with the ones in the FBI's Combined DNA Index System (CODIS). CODIS is a database of DNA profiles from crime scenes and known offenders. The profiles can also be compared to samples taken from victims and suspects.

START A CONVERSATION Tell students that DNA fingerprinting has been controversial in terms of its reliability. **Ask** What current events or past criminal trials have you read about that involve the reliability of DNA fingerprinting? *(Answers will vary.)* **Ask** Do you think that proven scientific discoveries should be allowed to exonerate people in jail for crimes that were judged using evidence examination techniques from the past? *(Generate a class discussion using a well-known criminal trial.)* Explain to the class that the closer the match between two samples of DNA, the more likely that the two samples are from one individual. Tell students that one of the reasons people are nervous about the reliability of DNA results is that the expense of scanning evidence increases with each region of DNA that is scanned. Explain that the reliability of DNA fingerprinting varies, depending on the number of regions scanned and the level of expertise of the interpreter. **Ask** If you were on a jury, which would you think is more reliable: an eyewitness or the results of DNA fingerprinting? *(Answers may vary, but inform students that the reliability of an eyewitness is 50:50.)*

Explain

DNA Technologies

USE AN ANALOGY Relate splicing an electrical wire to the methodology of recombinant DNA. If possible, have a student familiar with splicing electrical wire demonstrate the process. Introduce the complex topic of recombinant DNA methodology as simply removing a damaged section and replacing it with a newer and more reliable section that will allow the intended process to continue.

MAKE A CONNECTION Point out that the treatment of human diseases with recombinant proteins, though effective, is a replacement therapy. Explain that patients must have a continuous supply of the protein to remain asymptomatic. Ultimately, genetic engineers would like to develop methods for treating the cause of a genetically linked disorder by enabling the patient's own cells to produce a missing or faulty protein, an area of research referred to as gene therapy.

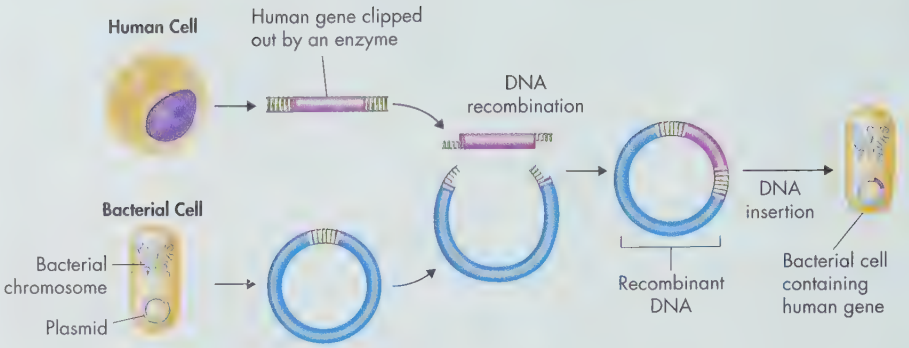

Figure 24.22
Recombinant DNA
Included here are the elements of an experiment involving recombinant DNA. In this experiment, DNA from one organism is inserted into the DNA of a different organism.

Recombinant DNA Technology Scientists have learned to manipulate genes by various methods. **Recombinant DNA technology consists of methods for cleaving a DNA chain, inserting a new piece of DNA into the gap created by the cleavage, and resealing the chain.** Figure 24.22 illustrates such a method. The altered DNA formed by this method is known as recombinant DNA.

Applications in Medicine The first practical application of recombinant DNA technology was to insert the gene for making human insulin into bacteria. Most people naturally make insulin, a polypeptide that controls levels of blood sugar. However, insufficient insulin production results in diabetes. The symptoms of diabetes can often be controlled by insulin injections. In the past, human insulin was not available for this purpose. Pig insulin, which is quite similar in structure to human insulin, was used as a substitute. Some patients, however, were allergic to pig insulin. Today, diabetic patients use the human form of insulin produced by bacteria that have been altered by recombinant DNA technology. Use of this insulin removes the need for the potentially dangerous use of pig insulin.

Other proteins produced by recombinant DNA technology are used as medicinal drugs. For example, an enzyme called tissue plasminogen activator (TPA) is used to dissolve blood clots in patients who have suffered heart attacks. Another protein, interferon, is thought to relieve or delay some of the debilitating effects of multiple sclerosis. Recombinant DNA technology is also being applied to the cure of genetic disorders in an experimental treatment known as gene therapy.

Applications in Agriculture In agriculture, new recombinant DNA techniques can make plants resistant to pests and weed killers and produce fruits and vegetables that are better suited for shipping and storage. The most common traits in genetically modified crops are herbicide resistance and insect resistance in corn, cotton, soybean, and canola.

Crops have also been genetically modified for pharmaceutical purposes. These so-called pharma crops are genetically modified to produce drugs to treat or prevent diseases such as cancer or AIDs. Genetically altered organisms have many potential benefits, but some people have concerns about their safety. There is also concern that genetically modified crops could contaminate other crops if they are grown and processed in close proximity to them.

Recombinant DNA

Recombinant DNA technology uses small circular DNA molecules called plasmids, which occur naturally in bacteria and in some yeasts. Once a human gene has been combined with the plasmid DNA, the recombinant molecule is reintroduced into bacteria. Because human DNA and bacterial DNA use the same bases and because the genetic code is universal, the bacteria translate the human gene in the recombinant DNA into protein exactly as they would their own genes. When grown in large incubators, the bacteria can produce massive quantities of the recombinant protein.

Cloning Ethical concerns were raised in 1997 when Scottish scientists announced the birth of a lamb named Dolly, shown in Figure 24.23. In normal animal reproduction, an offspring is a genetic mixture of the characteristics of both parents. Dolly, however, was a clone—an offspring of a single individual. A clone is an exact genetic copy of its parent because it is formed using the DNA of only that parent. Since the cloning of Dolly, other animals have also been successfully cloned, including cows, mice, and cats. The birth of cloned animals has raised the question of whether humans might eventually be cloned. Many people are concerned about some of the possible outcomes of cloning identical individuals. These situations are one aspect of more general concerns about the uniqueness of life.

Figure 24.23 Cloning
Polly and Dolly had no fathers. Dolly was cloned from a single cell taken from her mother. Polly was also cloned from a single cell that was genetically modified.
Infer ***How did Dolly's DNA compare with the DNA in her mother's cells?***

24.5 LessonCheck

29. **Review** What functions are performed by DNA and RNA?

30. **Review** What does a three-letter base sequence of DNA specify?

31. **Identify** What are three types of gene mutations?

32. **Identify** What methods are used in recombinant DNA technology?

33. **Describe** Describe how scientific methods might be applied to the process of DNA fingerprinting.

34. **Evaluate** Why do you think cloning is controversial? What are your personal thoughts on this matter?

Lesson Check Answers

29. DNA stores genetic information; RNA transmits genetic information.

30. an amino acid

31. substitution, addition, and deletion of a nucleotide

32. Answers might include the ideas of cleaving a DNA chain, inserting a new piece of DNA into the gap created by the cleavage, resealing the chain, and expressing the new gene product.

33. Forensic investigators use scientific methods when trying to solve a crime. At the crime scene, they make observations and collect evidence, including DNA samples. The investigators make hypotheses about how the crime was committed and who may be responsible. They can test these hypotheses by questioning suspects and comparing DNA fingerprints of the suspects with those left at the crime scene.

34. People have different opinions about issues such as the dignity of human life and interfering with nature.

Extend

Connect to LITERATURE

Have students read the autobiography of the Nobel Prize–winning chemist Arthur Kornberg. The title of his autobiography is *For the Love of Enzymes: The Odyssey of a Biochemist*. Kornberg provides an exceptionally readable historical account of the discovery and characterization of DNA and nucleic acids. This book documents many of the important biological discoveries made in the twentieth century. Assign students to utilize technology to make a timeline of the history of DNA.

Interested students may also wish to read James Watson's *The Double Helix*, a first-person account of the discovery of the structure of DNA.

Informal Assessment

Have students write a short paragraph comparing and contrasting DNA and RNA and explaining their roles in the production of proteins. Then have students complete the 24.5 Lesson Check.

Reteach

Display Figure 24.17 on an overhead projector. Use it to review the chemical and functional differences between DNA and RNA. Have students identify a complementary RNA strand for one of the strands of DNA shown in the figure.

Answers

FIGURE 24.23 Their DNA was the same.

LESSON 24.6

Key Objectives

24.6.1 DESCRIBE the function of ATP in the cell.

24.6.2 DESCRIBE what happens to biological molecules and energy during catabolism and anabolism.

24.6.3 EXPLAIN how nitrogen-fixing bacteria provide plants with a usable form of nitrogen.

Additional Resources

- Reading and Study Workbook, Lesson 24.6

Engage

CHEMISTRY & YOU Discuss with the class why a hummingbird's constant activity causes it to have a very high metabolic rate. **Ask** What is metabolic rate? *(how fast the body's chemical reactions proceed)*

Activate Prior Knowledge

Briefly review oxidation-reduction reactions. Then ask students to describe what they know about ATP from biology class. Provide biology textbooks for students to refer to for a more complete understanding of a living cell.

Foundations for Reading

BUILD VOCABULARY Explain that the suffix *-ism* means "process." Then have students write definitions of *metabolism, catabolism*, and *anabolism* in their own words.

24.6 Metabolism

CHEMISTRY & YOU

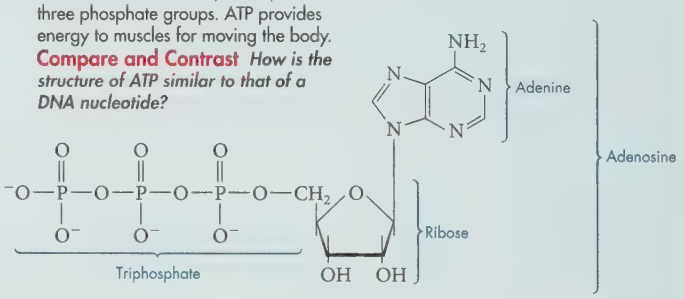
Q: *Why does a hummingbird eat so much?* A hummingbird eats more than its weight in food each day. Hummingbirds have a high body temperature, fast heart rate, and a fast breathing rate. All of these factors affect the hummingbird's metabolism. In this lesson, you will learn about the reactions that are part of an organism's metabolism.

Key Questions

- *What is the function of ATP in living cells?*
- *What happens to biological molecules and energy during catabolism and anabolism?*
- *How do nitrogen-fixing bacteria provide plants with a usable form of nitrogen?*

Vocabulary

- adenosine triphosphate (ATP)
- metabolism
- catabolism
- anabolism



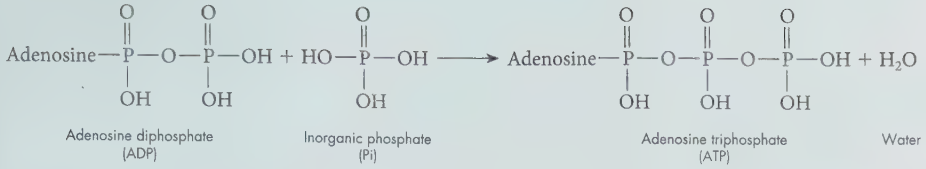
ATP

What is the function of ATP in living cells?

All living things need energy to function. **Adenosine triphosphate (ATP),** shown in Figure 24.24, is a molecule that transmits this energy in the cells of living organisms. The function of ATP can be compared to a belt connecting an electric motor to a pump. The motor generates energy capable of operating the pump. But if a belt does not connect the motor to the pump, the energy produced by the motor is wasted. You can think of ATP as the belt that connects the production and use of energy by cells. **In living cells, ATP is the energy carrier between the spontaneous reactions that release energy and nonspontaneous reactions that use energy.**

Recall that oxidation reactions, such as the combustion of methane in a furnace or the oxidation of glucose in a living cell, are spontaneous reactions that release energy. This energy can be captured when adenosine diphosphate (ADP) condenses with an inorganic phosphate group to become ATP. The addition of a phosphate group, called phosphorylation, occurs during certain biochemical oxidation reactions.

Figure 24.24 ATP
ATP is made of adenine, ribose, and three phosphate groups. ATP provides energy to muscles for moving the body.
Compare and Contrast *How is the structure of ATP similar to that of a DNA nucleotide?*



Focus on ELL

1 CONTENT AND LANGUAGE Ask students to state the key questions in their own words. Allow students with limited English to use their native languages for support.

2 FRONTLOAD THE LESSON Ask students what happens to their body temperature when they exercise or participate in a sport. *(Body temperature increases.)* Explain that this is a sign that their muscles and other tissues have increased their metabolic rate. Tell students that as they study the lesson, they should be alert for examples of chemical reactions that might be responsible for this increase.

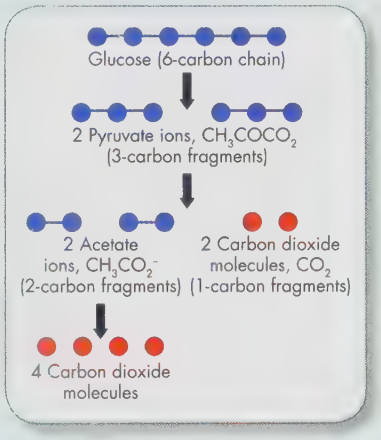
3 COMPREHENSIBLE INPUT Explain Figure 24.27 and read aloud the caption.

The formation of ATP efficiently captures energy produced by the oxidation reactions in living cells. Every mole of ATP produced by the phosphorylation of ADP stores about 30.5 kJ of energy. The reverse happens when ATP is hydrolyzed back to ADP: Every mole of ATP that is hydrolyzed back to ADP releases about 30.5 kJ of energy. Cells use this released energy to drive processes that would ordinarily be nonspontaneous. Because of its ability to capture energy from one process and transmit it to another, ATP is sometimes referred to as a high-energy compound; however, the energy produced by the breakdown of ATP to ADP is not particularly high for the breaking of a covalent bond. ATP is important because it occupies an intermediate position in the energetics of the cell. It can be formed by using the energy obtained from a few higher-energy oxidation reactions. The energy that is contained in the bonds of ATP can then be used to drive other cellular processes.

CHEMISTRY & YOU

Q: *Why does a hummingbird eat so much?*

Metabolism Reactions



What happens to biological molecules and energy during catabolism and anabolism?

Thousands of chemical reactions take place in the cells of a living organism. The entire set of chemical reactions carried out by an organism is known as the organism's **metabolism.** The reactions that occur in metabolism can be divided into two main processes, catabolism and anabolism.

Catabolism In metabolism, unneeded cellular components and the nutrients in food are broken down into simpler compounds by chemical reactions collectively called **catabolism.** Catabolic reactions release energy as well as produce simple compounds. **The degradation of complex biological molecules such as carbohydrates, lipids, proteins, and nucleic acids during catabolism provides the energy and the building blocks for the construction of new biological compounds needed by the cell.** Through the formation of ATP, catabolic reactions provide the energy for such needs as body motion and the transport of nutrients to cells where they are required. The oxidation reactions of catabolism also provide energy in the form of heat. These reactions help keep your body temperature constant at 37°C.

The complete oxidation of glucose to carbon dioxide and water is one of the most important energy-yielding processes of catabolism. Study Figure 24.25, which summarizes the major steps in the degradation of one glucose molecule to six molecules of carbon dioxide. The complete oxidation actually involves many reactions that are not shown. As you can see in the figure, the major carbon-containing reactants and products are named, and they are also referred to according to the number of carbons they contain.

Figure 24.25 Glucose Catabolism
The breakdown of glucose to carbon dioxide and water is one of the most important energy-yielding processes of catabolism.
Make Generalizations ***What happens to the number of carbon-carbon bonds from one step to the next?***

UbD Check for Understanding

What is the function of ATP in living cells?

Assess students' understanding about ATP by asking them to write an analogy that can be used to convey the function of ATP. Tell students that they cannot use the same analogy given in the textbook.

ADJUST INSTRUCTION If students are having trouble answering, have them reread the section entitled *ATP*. As a class, brainstorm various analogous situations. Then ask students to answer the question again.

READING STRATEGY After students read about catabolism and anabolism, ask them to create a diagram that shows how carbon moves from one type of metabolism to the other. Tell them to indicate where energy (ATP) comes into play.

Explain

ATP

APPLY CONCEPTS Have students compare the free energy changes associated with spontaneous and nonspontaneous processes. Explain that energy released by a reaction and available to do work is called free energy. Spontaneous processes, which favor formation of products, release free energy. Point out that it is the phosphate–oxygen anhydride bonds in ATP that store the chemical energy in ATP. When broken by water, these bonds release energy that is used to form new types of chemical bonds.

CHEMISTRY & YOU Hummingbirds need a lot of energy because they have a high metabolism. They get this energy from food.

CRITICAL THINKING Use Hess's law of heat summation to show how the free energy of ATP hydrolysis can be harnessed by the cell to drive a nonspontaneous reaction. Have students consider the reversible, nonspontaneous reaction:

$X \rightleftharpoons Y$; $\Delta G° = +21$ kJ / mol

Explain that normally, K_{eq} for this reaction is much less than 1, but if the reaction is coupled to the hydrolysis of ATP:

$ATP + H_2O \rightarrow ADP + P + H^+$

$\Delta G° = -30.51$ kJ/mol

$X + ATP + H_2O \rightarrow YP + ADP + H^+$

$\Delta G° = 9.5$ kJ/mol

Conversion of X to Y is driven forward by high intracellular concentrations of ATP.

MAKE A CONNECTION Explain that all living things require a continuous input of free energy. Point out that more than 50 percent of the free energy released by cellular reactions is used to cause other chemical changes; the rest is lost as heat. Compare this efficiency to that of the internal combustion engine—at most, 30 percent of the free energy of combustion is used to propel a car.

Answers

FIGURE 24.24 Like the nucleotides of DNA and RNA, ATP has a basic structure consisting of a phosphate group, a five-carbon sugar, and a nitrogen base. The sugar unit in both ATP and RNA is ribose.

FIGURE 24.25 The number of C—C bonds decreases.

Explain

Metabolism Reactions

APPLY CONCEPTS Explain that in the human body, glycogen is stored in skeletal muscles and the liver. Tell students that liver glycogen is used to maintain normal blood sugar levels whereas muscle glycogen is used solely for muscle work. Explain that large amounts of carbohydrates, including glycogen, are used by the body during athletic events that require power or speed. **Ask** What compounds provide the necessary energy during these events? *(carbohydrates)* **Ask** Why do you suppose some athletes use interval training, a technique that alternates rest and work phases? *(to train the biochemical energy pathways and to train the muscles used in an athletic activity)*

Extend

Tell students that proper training and diet can increase by more than a thousandfold the amount of glycogen stored after a training session. Have students research the training activities of a successful or favorite athlete of their choice. Students should be prepared to explain their findings to the class.

USE VISUALS Have students examine Figure 24.27. **Ask** Are there any inputs created by catabolism that are not reflected in outputs? *(no)* Discuss why this is so for an animal, for example. *(We need all these substances to live, and there must to be a way to break them down and use them to build a body.)*

Figure 24.26 Animal Metabolism
Organisms such as this mouse use the energy stored in the chemical bonds of food molecules to power their body processes.

The combustion of one mole of glucose to six moles of carbon dioxide and six moles of water, either by fire or by oxidation in a living cell, produces 2.82×10^3 kJ of energy. Cells that use oxygen may produce up to 38 moles of ATP by capturing the energy released by the complete oxidation of a single mole of glucose! The large amount of ATP produced from the oxidation of glucose makes it the likeliest mode of energy production for most kinds of cells. In fact, if glucose is available, brain cells use no other source of carbon compounds for energy production. The need for energy and building blocks is the reason why all organisms, such as the field mouse shown in Figure 24.26, require food.

Anabolism Some of the simple compounds produced by catabolism are used to synthesize more-complex biological molecules—carbohydrates, lipids, proteins, and nucleic acids—necessary for the health and growth of an organism. The synthesis reactions of metabolism are called **anabolism.** Unlike catabolism, which releases energy, anabolism uses energy.

Figure 24.27 gives an overview of the relationship between catabolism and anabolism. Nutrients and unneeded cell components are degraded to simpler components by the reactions of catabolism. The oxidative reactions of catabolism yield energy captured in the formation of ATP. **In anabolism, the products and the energy of catabolism are used to make new compounds and cell parts needed for cellular life and growth.** You already know that energy produced by physical and chemical processes is of little value unless the energy can be captured to do work. If it is not captured, the energy is lost as heat. The chemical energy produced by catabolism must have some means of being used for the chemical work of anabolism. The ATP molecule is that means of transmitting energy.

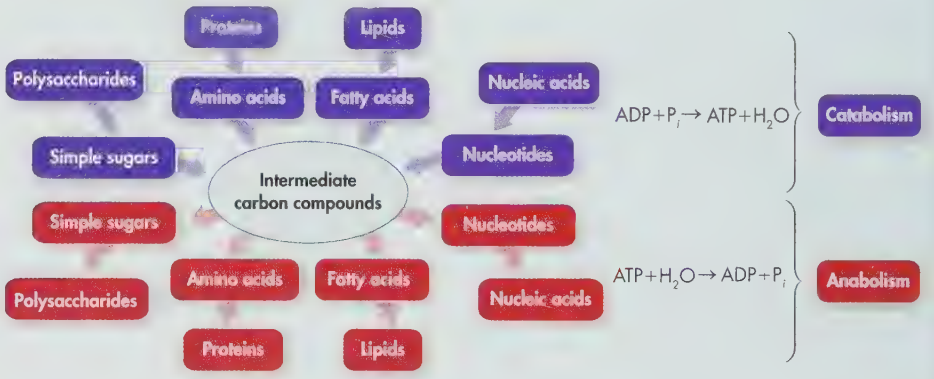


Figure 24.27 Catabolism and Anabolism
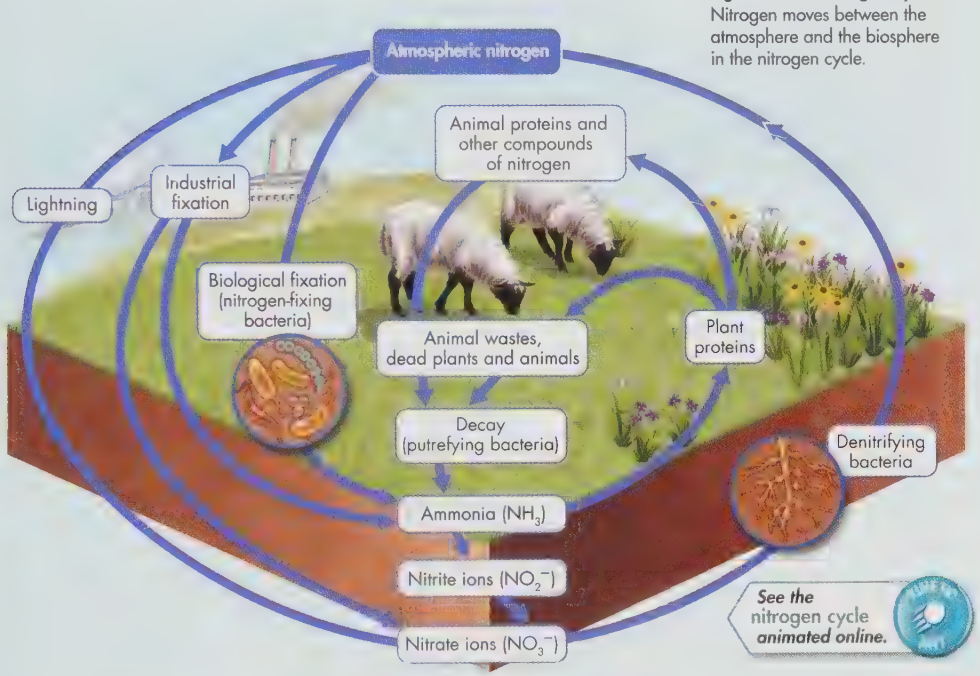
Simple compounds produced by catabolism are used in the synthesis reactions of anabolism.
Apply Concepts *What part of metabolism releases energy? What part uses energy?*

Differentiated Instruction

LPR LESS PROFICIENT READERS Have students create separate cards for all the steps in glucose breakdown that are shown in Figure 24.25. Students should expand on the shorthand version in the visual, using words or chemical structures, so that each step makes sense to them. They can shuffle their cards and have another student put them into the correct sequence.

L1 STRUGGLING STUDENTS Have students create a T-chart to organize the similarities and differences between catabolism and anabolism in their own words.

ELL ENGLISH LANGUAGE LEARNERS Supply students with enlarged copies of Figure 24.27 and Figure 24.28. Pair beginning and intermediate speakers with advanced speakers of the same language. Encourage advanced speakers to explain points of confusion to their partners in their native language, and allow students to make native language notes on their handouts.



The Nitrogen Cycle

How do nitrogen-fixing bacteria provide plants with a usable form of nitrogen?

You have learned that the biological molecules taken into an organism's body as nutrients in food are broken down during catabolism. Food contains carbohydrates, proteins, lipids, nucleic acids, vitamins, and minerals. These nutrients are composed mainly of carbon, hydrogen, and oxygen atoms. Many biological compounds, such as proteins, contain nitrogen as well. Although Earth's atmosphere is 78 percent nitrogen gas, no animals and only a few plants can use this form of nitrogen to make nitrogen-containing compounds. However, certain bacteria can convert nitrogen gas into usable forms in a process called nitrogen fixation. **Nitrogen-fixing bacteria reduce atmospheric nitrogen ($N_2(g)$) to ammonia ($NH_3(g)$), a water-soluble form of nitrogen that can be used by plants.** In soil and biological fluids, most ammonia is present as ammonium ions.

Plants incorporate ammonia into biological nitrogen compounds such as proteins, nucleic acids, and ATP. Because animals cannot synthesize these compounds, they get them by eating plants or other animals that eat plants. When these plants and animals die, they decay with the aid of bacteria. Decaying matter returns nitrogen to the soil as ammonia, nitrite ions (NO_2^-), or nitrate ions (NO_3^-). Moreover, some nitrogen gas is returned to the atmosphere. This flow of nitrogen between the atmosphere and Earth and its living creatures is the nitrogen cycle, shown in Figure 24.28.

Figure 24.28 Nitrogen Cycle Nitrogen moves between the atmosphere and the biosphere in the nitrogen cycle.

UbD Check for Understanding

The Essential Question **What are the functions of anabolism and catabolism in a cell?**

Assess knowledge of metabolism by allowing students to write or verbalize a scenario that depicts the functions of anabolism and catabolism.

ADJUST INSTRUCTION If students are having difficulty distinguishing between catabolism and anabolism, have them read the sections entitled *Catabolism* and *Anabolism* again. Then remind students that catabolic reactions break bonds, releasing energy in the form of ATP. Anabolic reactions use energy from ATP to make bonds.

Explain

The Nitrogen Cycle

USE VISUALS Direct students' attention to Figure 24.28. Point out that nitrogen often is the limiting factor in how many plants can grow to maturity in a system. Explain that some plants are adapted to low-nitrogen environments, where faster-growing plants are unable to obtain adequate nitrogen to take over the habitat. Tell students that release of extra nitrogen from fertilizers would allow the faster-growing plants to outcompete the low-nitrogen specialists, eventually eliminating the low-nitrogen plants from the habitat.

Answers

FIGURE 24.27 Catabolism releases energy; anabolism uses energy.

Evaluate

Informal Assessment

Display the diagram of the carbon cycle, from page 840, and the diagram of the nitrogen cycle side-by-side. Ask students to compare the two cycles. **Ask** Where does energy, in either diagram, come into play? What is its source? *(Students should be able to indicate which pathways release energy and which require energy to proceed.)* Then have students complete the Lesson 24.6 Lesson Check.

Reteach

Draw a schematic diagram on the board that illustrates the exchange of energy between anabolic and catabolic reactions. Connect the terms *ATP* and *ADP* by up and down arrows. Label the up arrow *anabolism*. In anabolic reactions, small molecules are put together to form larger ones. Explain that these nonspontaneous processes must be coupled to the free energy of ATP hydrolysis; thus, ADP is produced during anabolic reactions. Label the down arrow *catabolism*. Explain that in catabolic reactions, large molecules are broken down; catabolic reactions most often release energy that can be used to drive the synthesis of ATP.

Biological Nitrogen Fixation Nitrogen-fixing bacteria are of two types: free-living and symbiotic. Free-living bacteria lead an independent existence in soil. Symbiotic bacteria, such as *Rhizobium*, live in a mutually beneficial arrangement with plants. Symbiotic bacteria live in nodules on the roots of legumes, such as alfalfa, clover, peas, and beans. These root nodules are shown in Figure 24.29. Soil fertility can be improved by plowing nitrogen-rich legumes back into the ground instead of harvesting them.

Industrial Nitrogen Fixation Modern agriculture uses an enormous quantity of nitrogen, which plays a role in the nitrogen cycle. For the past several years, the daily amount of atmospheric nitrogen fixed by industrial processes in the production of fertilizers has probably exceeded the amount fixed by living organisms in Earth's forests and oceans. Nitrogen fertilizers enter the biosphere when they are taken up by plants. In addition, a small amount of atmospheric nitrogen is fixed by lightning discharges, which produce the soluble nitrogen oxides (NO, NO_2, N_2O_4, and N_2O_5).

Figure 24.29
Nitrogen-Fixing Bacteria
The bumps on these plant roots contain bacteria that live in a symbiotic relationship with the plant. The plant gets nitrogen in a form it can use, and the bacteria get food in the form of sugars that the plant makes during photosynthesis.

24.6 LessonCheck

35. **Explain** What is the role of ATP in energy production and energy use in living cells?

36. **Explain** What is the function of catabolism in the cells of living organisms?

37. **Sequence** How does anabolism make use of the products of catabolism?

38. **Identify** What form of nitrogen is supplied to plants by nitrogen-fixing bacteria?

39. **Identify** How many moles of ATP are formed from the complete oxidation of one mole of glucose in a cell that uses oxygen?

BIG IDEA
CHEMISTRY AS THE CENTRAL SCIENCE

40. Write a paragraph that describes how nitrogen moves between the atmosphere and the biosphere. (*Hint:* Use atmospheric nitrogen as the starting point in your description of the process.)

Lesson Check Answers

35. ATP transmits energy in the body. Energy is released and captured in the bonds of ATP when the bonds of ATP are broken.

36. Catabolism is the subset of metabolic reactions that involves degradation of complex molecules and production of energy.

37. Catabolic reactions provide the energy and the building blocks for the construction of new compounds needed by the cell in anabolism.

38. Atmospheric nitrogen is converted to ammonia and ammonium ions.

39. as many as 38 moles of ATP

40. The nitrogen cycle is the flow of nitrogen between the atmosphere and biosphere. Atmospheric nitrogen is converted to ammonia and ammonium ions by nitrogen-fixing bacteria. Plants and then plant-eating organisms synthesize nitrogen-containing compounds. The decay of these plants and animals returns nitrogen to the atmosphere.

DNA Testing

Would you want to know if you are predisposed to a treatable disease, such as diabetes or breast cancer? What about an incurable disease, such as Huntington's disease? The answers to these questions, and many more, are only a drop of saliva away.

In the past few years, researchers have learned how to test for hundreds of genetic disorders using genetic testing. Genetic testing involves analyzing a person's DNA to determine changes in genes that may indicate a specific disorder. The DNA used for the tests can be obtained from a sample of blood, urine, or even saliva. In fact, today you can mail a saliva sample to a lab, and then view your test results online!

Genetic testing can be valuable in determining a person's likelihood of developing a treatable disease. However, learning of a genetic predisposition for a disease that currently has no treatments or cures can cause anxiety or despair. In addition, there are many ethical concerns involved in genetic testing, including who gets access to the test results and how many actual tests are performed on the DNA. The information in DNA is much greater than just the specific disease a lab could test for. Because of these concerns, it is important to consider all the consequences of knowing your genetic information before getting tested.

DNA MUTATIONS Alterations in the order of the bases in DNA cause gene mutations, which can lead to diseases.

TESTING FROM HOME At-home tests involve collecting saliva or blood samples. The sample is then sent to a lab, which analyzes the DNA for mutations known to correspond to different diseases and disorders.

Take It Further

1. Identify What are some of the possible benefits of genetic testing? What are some of the possible risks?

2. Form an Opinion Would you want to be tested for potential genetic disorders? Why or why not?

21st Century Learning To be successful in the 21st century, students need skills and learning experiences that extend beyond subject matter mastery. The project below helps students build the following 21st Century Skills: *Global Awareness; Financial, Economic, Business, and Entrepreneurial Literacy; Civic Literacy; Critical Thinking and Problem Solving; Communication and Collaboration; Flexibility and Adaptability; Social and Cross-Cultural Skills.*

DEBATING DNA Pose the following challenge to your students. *Suppose a bill has been introduced in Congress to require genetic testing of all newborn infants. Would you be in favor of its passage or against it? Debate the issue with others in your class.*

- Divide the class into teams of two students each.
- Each team should research both sides of the issue and should be prepared to argue in favor of either position and against the opposing viewpoint.
- Students should consider both the societal effects and the moral considerations of DNA testing, as well as financial effects.

CHEMISTRY & YOU Have students read the passage and study the photos showing applications of DNA testing. Lead them in a discussion of current applications of DNA testing. Then, have students look back at DNA Typing on page 859 and have them compare and contrast DNA typing to testing individuals for genetic disorders.

Explain

USE AN ANALOGY Explain that DNA testing is similar to trying to solve a coded message. Like a coded message, DNA contains a lot of details that are not easily understood. Similar to the way that analyzing a code can help reveal those details, testing DNA and analyzing it can reveal a lot of information about an organism.

Extend

Connect to BIOLOGY

DNA testing is an important tool that biologists use to analyze the evolutionary path between ancient and modern species. By analyzing the DNA remains of ancient organisms, scientists can compare them with modern species to determine differences and similarities. Have students research the use of DNA testing in this manner, and have them identify a species that has been recently reclassified or an evolutionary relationship that has been discovered as a result of DNA testing. Have students share their findings with the class.

TAKE IT FURTHER

1. Answers will vary. One benefit is that people can take preventative measures. The results must be kept private, though. People might not qualify for insurance coverage or employment opportunities could be adversely affected if the results are revealed.
2. Answers will vary.

Review and Assessment Materials

PROBLEM SETS Have students practice more chemical quantity problems by using the Chapter 17 Online Problem Set.

Study Tip

STUDY WITH A FRIEND Offer students the following advice: Quiz each other, compare notes, and discuss discrepancies. Organize the types of biomolecules you learned about in this chapter. You could make a chart that compares the different types of chemicals, or you could make a flowchart of processes. Work together to make sure you include all the important points.

24 Study Guide

BIG IDEA
CHEMISTRY AS THE CENTRAL SCIENCE

There are four main types of biological molecules. Most carbohydrates are polymers that release energy when broken down. Proteins are polymers of amino acids and are needed for most chemical reactions in cells. Lipids are water-insoluble and can be used for long-term energy storage. Nucleic acids are polymers of nucleotides. The nucleic acid DNA carries the instructions for a cell. Catabolic reactions break down biological molecules to provide energy and building blocks for the cell. Anabolic reactions build biological molecules to store energy and make new cell parts.

24.1 A Basis for Life

- The two major cell types that occur in nature are prokaryotic cells and eukaryotic cells.
- Photosynthesis uses sunlight to reduce CO_2 to compounds that contain C—H bonds, mainly in the form of glucose.

- photosynthesis (839)

24.2 Carbohydrates

- Most carbohydrates have the general formula $C_n(H_2O)_n$.

- carbohydrate (841)
- monosaccharide (841)
- disaccharide (842)
- polysaccharide (843)

24.3 Amino Acids and Their Polymers

- An amino acid has a carboxyl group, an amino group, a hydrogen atom, and an R group bonded to a central carbon atom.
- Differences in the amino acid sequence result in differences in the properties of peptides.
- Enzymes increase reaction rates.

- amino acid (844)
- peptide (845)
- peptide bond (845)
- protein (845)
- enzyme (847)
- substrate (847)
- active site (847)

24.4 Lipids

- Lipids tend to dissolve readily in organic solvents, whereas carbohydrates and proteins tend to dissolve in water.

- lipid (850)
- triglyceride (850)
- saponification (851)
- phospholipid (851)
- wax (852)

24.5 Nucleic Acids

- DNA stores information needed to make proteins and governs the reproduction of cells. RNA transmits information stored in DNA during protein synthesis.
- A sequence of three bases of DNA is required to specify one amino acid in a peptide.
- Gene mutations occur when one or more nucleotides in DNA are substituted, added, or deleted.
- Examples of DNA technology include DNA typing, production of bacteria that make human proteins, genetically modifying foods and animals, and cloning.

- nucleic acid (854)
- nucleotide (854)
- gene (856)

24.6 Metabolism

- In living cells, ATP is the energy carrier between the spontaneous reactions that release and the nonspontaneous reactions that use energy.
- The degradation of biological molecules during catabolism provides the energy and the building blocks for making new compounds. In anabolism, new compounds needed for cellular life and growth are made from the products of catabolism.
- Nitrogen-fixing bacteria reduce atmospheric nitrogen to ammonia, a water-soluble form of nitrogen that can be used by plants.

- adenosine triphosphate (ATP) (862)
- metabolism (863)
- catabolism (863)
- anabolism (864)

UbD Performance Tasks

DNA TECHNOLOGY Separate the class into two debate teams. Have them spend a class period debating DNA technology. One of the teams should create an argument for the technology, and the other should create an argument against the technology. Make sure each member of each team has a clearly defined role. Roles can be leader, researcher, presenter, artist, organizer, strategizer, and so on.

CATABOLISM VS. ANABOLISM Have students create a unique diagram that correctly depicts the functions of anabolism and catabolism. Diagrams should include how carbohydrates, amino acids, lipids, and nucleic acids relate to each function.

Focus on ELL

5 ASSESS UNDERSTANDING Have students create a portfolio for this chapter. Include various types of assignments, based on each student's language proficiency.

BEGINNING

LOW Include lists, models or pictures of models, or diagrams created by the student.

HIGH Include copies of the graphic organizers used to take notes or show how carbohydrates, amino acids, lipids, and nucleic acids relate to one another.

INTERMEDIATE

LOW Include any prereading predictions about lesson topics, as well as the results of those predictions.

HIGH Include any lab write-ups that were assigned during the chapter.

ADVANCED: LOW/HIGH Include an essay on the pros and cons of two uses of DNA technology.

24 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

24.1 A Basis for Life

41. What is the main difference between a prokaryotic and a eukaryotic cell?

***42.** Explain what happens in photosynthesis.

43. Write a balanced equation for the complete oxidation of glucose.

44. Describe three organelles found in eukaryotic cells. Give a function of each organelle.

24.2 Carbohydrates

45. Name two important monosaccharides.

46. Where in nature are glucose and fructose found?

***47.** How does the carbonyl functional group differ in glucose and fructose?

48. Which monosaccharides combine to form the disaccharide sucrose?

49. What is the product of the complete hydrolysis of starch? Of glycogen?

50. What product is formed when cellulose is broken down?

24.3 Amino Acids and Their Polymers

51. What is the name given to the bond connecting two amino acids in a peptide chain?

52. How many peptide bonds does the tripeptide Ser—Gly—Phe have? Explain.

***53.** Describe two common patterns found in the folding of protein chains.

54. Are the structures of the following two tripeptides the same? Explain.

a. Ala—Ser—Gly **b.** Gly—Ser—Ala

55. Describe the function of an enzyme.

56. What is an enzyme-substrate complex? How does it form?

24.4 Lipids

57. Distinguish between a fat and an oil.

58. What is a triglyceride?

59. What is a soap?

60. Draw structural formulas for the products of the complete hydrolysis of tristearin.

61. Draw a simple representation of a lipid bilayer.

62. What two types of compounds combine to form a wax?

24.5 Nucleic Acids

63. What two types of nucleic acids do cells have?

***64.** What are the components of a nucleotide?

65. What is the structural difference between the sugar unit in RNA and the sugar unit in DNA?

66. What type of bonding helps hold a DNA double helix together?

67. Which of the following base pairs are found in a DNA molecule: A—A, A—T, C—G, G—A, A—U, T—U?

68. How many bases specify an amino acid in the genetic code?

***69.** What are the consequences of a substitution of one base for another in DNA? Give an example.

***70.** What is the basis for identifying an individual by DNA profiling?

71. What is recombinant DNA?

24.6 Metabolism

72. Write an abbreviated, balanced equation for the hydrolysis of ATP to ADP.

73. Where do the complex biomolecules your body degrades during catabolism come from?

***74.** How are catabolism and anabolism related?

75. Describe the nitrogen cycle in your own words.

76. What is the source of raw materials used in anabolic reactions?

77. What is meant by industrial nitrogen fixation? What is produced during this process?

Understand Concepts

***78.** The formula for palmitic acid is $CH_3(CH_2)_{14}CO_2H$. A popular soap is mostly sodium palmitate. Draw a structural formula for sodium palmitate.

68. Three

69. A substitution of one base for another may have no effect because the amino acid specified by the DNA code is not changed. Or a substitution of one base for another can result in a gene mutation in which the amino specified by the DNA code is changed.

70. Each individual's DNA is unique.

71. altered DNA that contains a foreign gene

LESSON 24.6

72. $ATP + H_2O \rightarrow ADP + P_i$

73. foods or existing body tissues

74. In catabolism, molecules are broken down and energy is captured. These products are used to make biomolecules in anabolism.

75. N_2 is converted to NH_3, which is taken up by plants, which are eaten by animals. Decaying organisms return N_2 to the air.

76. products of catabolism

77. Atmospheric nitrogen is reduced to ammonia by industrial processes.

UNDERSTAND CONCEPTS

78.

$$CH_3(CH_2)_{14}-\overset{\overset{O}{\|}}{C}-O^-Na^+$$

sodium palmitate

Evaluate

Answers

LESSON 24.1

41. A eukaryotic cell has a cell membrane and organelles. Prokaryotic cells have a cell membrane, but lack organelles.

42. Photosynthetic organisms use the sun's energy to synthesize carbon compounds from CO_2 and H_2O

43. $C_6H_{12}O_6 + 6O_2 \rightarrow 6CO_2 + 6H_2O$ + energy

44. *Sample answer:* nucleus (cellular reproduction); mitochondria (cellular energy production); lysosomes (digestion of substances)

LESSON 24.2

45. glucose and fructose

46. Glucose is found in blood, corn, and grapes. Fructose is found in honey and many fruits.

47. Glucose is an aldehyde; fructose is a ketone.

48. glucose and fructose

49. glucose; glucose

50. glucose

LESSON 24.3

51. peptide bond

52. two

53. Peptide chains fold into helixes or into pleated sheets in which peptide chains lie side by side.

54. No; Both peptides contain alanine, serine, and glycine, but the sequences are different.

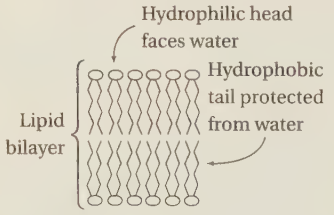
55. Enzymes catalyze biological reactions.

56. complex formed when an enzyme and substrate bind to each other

LESSON 24.4

57. At room temperature, animal fats are solid; plant oils are liquid.

58. triester of glycerol and fatty acids



59. alkali metal salt of a fatty acid

60.

$$\begin{array}{l} CH_2OH \\ | \\ CHOH + 3CH_3(CH_2)_{16}-\overset{\overset{O}{\|}}{C}-O^-Na^+ \\ | \\ CH_2OH \end{array}$$

Glycerol Sodium stearate

61.

62. long-chain fatty acid and long-chain alcohol

LESSON 24.5

63. DNA and RNA

64. phosphate group, sugar unit, nitrogen base

65. Ribose has one more oxygen.

66. hydrogen bonding

67. A–T and C–G

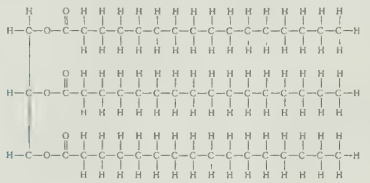
ASSESSMENT

Evaluate

Answers

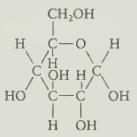
79. The negatively charged hydrophilic phosphate heads interact favorably with water.
80. **a.** Arg-Gly-Cys-Asn **b.** Arg-Gly-Cys-Asn
81. **a.** triglyceride **b.** glucose **c.** dipeptide
82. C-G-x-C-C-x-T-C-A(or G); There are multiple codes for the same amino acid.
83. G-C-T-A-G-G-T
84. **a.** amino acid
b. monosaccharide (simple sugar)
c. nucleotide
85. permit passage of nutrients into cells
86. No; three code words specify the termination of a peptide chain.
87. many applications in medicine and agriculture
88. 30.5 kJ/mol × 38 mol/2.82 × 10^3 kJ/mol × 100% = 41.1%
89. about 275 mol ATP
90. The shape of the cellulose and starch molecules are different; humans lack enzymes necessary to cleave cellulose to glucose monomers.
91. A substrate molecule or molecules binds to the active site of the enzyme to form an enzyme-substrate complex.
92. Coenzymes must be present for an enzyme-catalyzed reaction to occur.
93. evidence from fossilized bacteria
94. Mutations could occur that would change how the organism constructs a protein.
95. Photosynthesis provides the carbon compounds that plants and animals need to exist.
96. monosaccharides: single simple sugar; glucose, fructose disaccharides: two linked monosaccharide units; sucrose polysaccharide: many linked monosaccharide units; starch, glycogen, cellulose
97. A carboxylic acid group of one amino acid and amino group of another amino acid undergo condensation polymerization to form an amide (peptide) bond.
98. hydrogen bonding between A-T (A-U in RNA) and G-C in DNA; helps hold DNA in double helix

THINK CRITICALLY



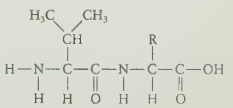
99. CO_2 cannot produce energy through oxidation. Glucose can be oxidized to CO_2 and produce energy.
100. Inside the helix; strands must unwind
101. Substitution of one base could result in no change in the amino acid sequence of a protein (if there are multiple code words for the amino acid), or a different amino acid, which could be damaging or helpful to the organism. A base added to the start of the gene would result in a nonsense amino acid sequence for the protein produced by the gene. A base added to the end of the gene could make the termination codon untranslatable, and the protein product might not terminate.

79. Why are the hydrophilic heads located on the outsides of the cell membrane?



80. Consider the following sequence of DNA: GCC–CCA–ACG–TTA.
a. Using the code words for amino acids in Table 24.2 on page 857, write the amino acid sequence formed by translation of the DNA sequence into a peptide.
b. What amino acid sequence would result from the substitution of adenine (A) for the second cytosine (C)?

81. Identify or classify each of the following biological molecules.



a.

b.

c.

***82.** Use Table 24.2 on page 857 to write a base sequence for DNA that codes for the tripeptide Ala—Gly—Ser. Why might your answer be different from the answers of your classmates?

83. A segment of a DNA strand has the following base sequence: CGATCCA. Write the base sequence that would be found on the other strand in the double helix.

84. Which type of monomer produces each of the following polymers?
a. protein
b. polysaccharide
c. nucleic acid

85. What is one function of membrane proteins?

***86.** Does every code word in DNA specify an amino acid in protein synthesis? Explain.

87. What are some of the outcomes of recombinant DNA research?

***88.** The complete oxidation of glucose releases 2.82 × 10^3 kJ/mol of energy, and the formation of ATP from ADP requires 30.5 kJ/mol. What percent of the energy released in the complete oxidation of glucose is captured in the formation of ATP?

***89.** An average adult expends about 8400 kJ of energy every day. How many moles of ATP must be converted to ADP to provide this amount of energy?

90. Why can't humans digest cellulose, considering that it is made of the same monomers as starch?

91. How is an enzyme-substrate complex formed in the enzyme's active site?

92. What role do coenzymes play in metabolism?

93. Suggest a reason why prokaryotic cells are thought to be more ancient than eukaryotic cells.

94. What are the possible consequences of an error in DNA sequence?

95. Explain why photosynthesis might be considered the most important chemical process on Earth.

***96.** Describe the differences among monosaccharides, disaccharides, and polysaccharides. Give examples of each type of carbohydrate.

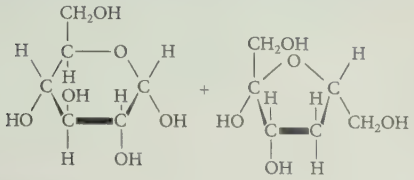
97. Describe how amino acids join to form a peptide bond.

***98.** What is base pairing? How does base pairing relate to the structure of DNA?

Think Critically

99. **Explain** Interpret this statement: "Carbon dioxide is an energy-poor molecule, but glucose is an energy-rich molecule."

100. **Sequence** In the DNA double helix, where are the base pairs located in relation to the backbone structure: inside the double helix or outside the double helix? What must happen before the protein-making machinery of the cell can "read" the code words formed by the DNA bases?



101. **Explain** Which type of gene mutation do you think will do more damage to an organism: a substitution mutation in which one base is substituted for another base or an addition mutation in which a base is added to a sequence of bases? Explain.

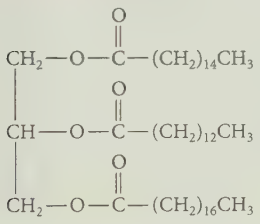
102. Predict Suggest a reason why a bean plant might not grow well if planted in sterilized soil.

103. Identify What class of polymer is formed from each of the following monomers?

a. amino acids
b. monosaccharides
c. nucleotides

***104. Interpret Diagrams** Complete the following equation by drawing the structural formulas of the products:

Enrichment



105. Compare and Contrast Compare the structure of a DNA nucleotide with an RNA nucleotide.

106. Compare Describe the structural features all amino acids have in common. What structural features differ among the amino acids?

***107. Identify** Using structural formulas, write a chemical equation for the formation of a dipeptide from two amino acids. What functional group does the reaction create?

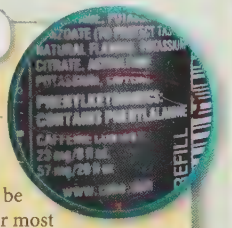
108. Cause and Effect Explain why cell growth stops when the dietary intake of nutrients is insufficient.

109. Interpret Diagrams The following compound is hydrolyzed by boiling with sodium hydroxide. What are the saponification products?

110. Identify What causes the spontaneous formation of a lipid bilayer?

111. Explain Peptide chains fold and bend into three-dimensional shapes. Suggest how a peptide chain is held in this 3-D shape.

***112. Interpret Diagrams** A sequence of nine bases in a gene codes for the amino acid sequence Trp-Met-Met. What is the sequence of bases in this DNA fragment? Use Table 24.2 on page 857 to help you. Could you determine the base sequence for certain if the amino acid sequence were Trp-Met-Leu? Why or why not?



Write About Science

113. Explain Write a paragraph explaining how cells are able to selectively absorb certain ions and molecules while excluding other materials.

114. Connect to the BIGIDEA Choose one of the biological molecules discussed in this chapter. Write a paragraph describing how the elements and structure of the molecules relate to the function of the molecules.

CHEMYSTERY

Phenyl-what?

Phenylalanine is an amino acid, a monomer of proteins. So, how could phenylalanine be hazardous to your health? For most people, phenylalanine is not a health concern. But it is a concern for people who have the genetic disorder phenylketonuria, or PKU. Normally, phenylalanine is converted by the body to another amino acid, tyrosine. People with PKU lack the enzyme that is required to convert phenylalanine to tyrosine. When this happens, phenylalanine accumulates to toxic levels in the body. PKU is treated by eating a diet low in phenylalanine (the body still needs a small amount phenylalanine).

115. Infer Given that phenylalanine is an amino acid, which types of foods would you expect to be high in phenylalanine?

116. Connect to the BIGIDEA Why does a nutritionist need to understand chemistry?

CHEMYSTERY

USE AN ANALOGY Have students read over the CHEMystery. Engage them in a discussion about what they have learned about amino acids and proteins. Remind students that proteins are needed for almost all chemical reactions in the body. Help students understand phenylketonuria (PKU) by using an analogy of getting a sunburn. Explain that your body needs sunlight to produce vitamin D, but too much sunlight can damage your skin. Similarly, your body needs the amino acid phenylalanine, but for people with the PKU disorder, too much phenylalanine is harmful. It can lead to poor development and brain disorders.

CHEMYSTERY ANSWERS

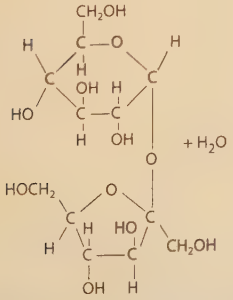
115. foods that contain protein such as poultry, eggs, beans, and brown rice

116. Nutritionists treat and prevent illnesses by making modifications to a patient's diet. They need to know how the chemicals in food affect your health. They also need to which biological molecules are contained in certain foods and how these biological molecules affect your health.

112. A-C-C-T-A-C-T-A-C; no, Leu has 6 possible code words.

WRITE ABOUT SCIENCE

113. The cell wall is selectively permeable meaning that only certain molecules and ions can enter or leave the cell. The three ways in which molecules and ions can enter or leave the cell are passive transport, active transport, and in a vesicle. Small molecules or ions cross by transport. Larger molecules cross within a vesicle. Answers should include a brief description of these three ways.



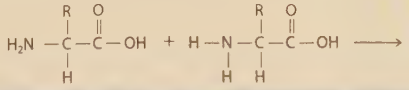
114. Students can write about carbohydrates, amino acids, lipids, nucleic acids, and ATP.

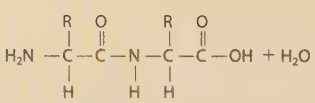
Answers

102. Bacteria necessary for nitrogen fixation might be killed by sterilization of the soil.

103. a. peptides and proteins
b. polysaccharides
c. polynucleotides (RNA and DNA)

104.





ENRICHMENT

105 A nucleotide consists of a phosphate group, a five-carbon sugar unit, and a nitrogen base. In DNA, the sugar is deoxyribose; in RNA, the sugar is ribose. In DNA, the bases may be A, G, T, or C; in RNA, the bases may be A, G, U, or C.

106 Every amino acid consists of a central carbon atom bonded to an amine group, a carboxyl group, a hydrogen atom, and a side chain. Different amino acids have different side chains.

107. An amide goup is formed by the reaction.

108. Nutrients supply carbon compounds, ions, and energy needed for growth. The (insufficient) food primarily is used for energy production necessary to sustain the cell.

109. glycerol + a soap

110. Phospholipids have hydrophobic tails that exclude water and polar heads that dissolve in water.

111. hydrogen bonds between adjacent parts of folded chains and covalent bonds between side-chain groups of cysteine

ASSESSMENT

Evaluate

Answers

CUMULATIVE REVIEW

117. The particles in real gases have volumes and are attracted to one another.

118. a and b are electrolytes. c and d are nonelectrolytes.

119. **a.** 0.519°C **c.** 0.238°C
b. 0.209°C **d.** 0.227°C

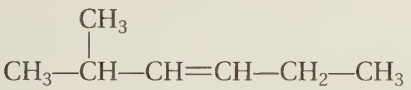
120. 1.71×10^1 kJ heat absorbed

121. Besides being composed of highly combustible material, the needles have a large surface area that increases their rate of combustion.

122. The equivalents of acid and base must be equal.

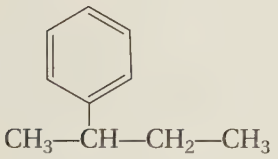
123. **a.** 4.15 **c.** 12.79
b. 5.26 **d.** 10.36

124. **a.** fluorine **b.** oxygen **c.** chlorine



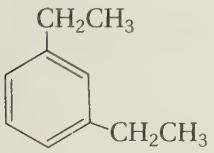
125. Oxidation always occurs at the anode. In the voltaic cell the anode is the negative electrode.

126. The nickel wire would be silver-plated.



127. **a.** Cu **c.** Ag **e.** Cd
b. Ni **d.** Fe **f.** Cu

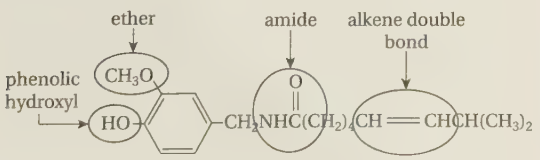
128. **a.** $CH_3—CH_2—CH_2—CH_2—CH_2—CH_2—CH_3$



b.

c.

d.



129. **a.** 1-pentene
b. cyclononane
c. hexane
d. decane

130. **a.** cyclopentane
b. 2-methyl-2-propanol
c. 3-pentanone

131. **a.** $CH_3CO_2CH_3$ **b.** $CH_3CHOHCOOH$

132. **a.** polytetrafluoroethene (non-stick cookware)
b. polyethylene (plastic bags and containers)
c. polyvinyl chloride (PVC pipe)
d. polystyrene (electric insulation)

133.

Cumulative Review

117. Describe two factors that cause real gases to depart from the ideal gas law.

118. Characterize these compounds as electrolytes or nonelectrolytes.

a. NaCl **c.** CCl_4
b. $CuSO_4$ **d.** H_2O

***119.** Calculate the boiling-point elevation for these aqueous solutions.

a. 0.507*m* NaCl **c.** 0.155*m* $CaCl_2$
b. 0.204*m* NH_4Cl **d.** 0.222*m* $NaHSO_4$

***120.** How much heat (in kJ) is released or absorbed when 0.265 mol of sodium bicarbonate is decomposed according to the reaction below?

$$2NaHCO_3(s) \rightarrow Na_2CO_3(s) + H_2O(g) + CO_2(g)$$
$$\Delta H = 129 \text{ kJ}$$

121. Explain why the needles on a dried-out fir tree can burn with almost explosive rapidity.

122. What must be true at the end point of an acid-base titration?

123. Calculate the pH of each of the following solutions:

a. $[H^+] = 7.0 \times 10^{-5} M$
b. $[OH^-] = 1.8 \times 10^{-9} M$
c. $[OH^-] = 6.1 \times 10^{-2} M$
d. $[H^+] = 4.4 \times 10^{-11} M$

124. Identify the oxidizing agent in each reaction.

a. xenon + fluorine ⟶ xenon tetrafluoride
b. sulfur + oxygen ⟶ sulfur trioxide
c. gaseous chlorine + aqueous sodium bromide ⟶ aqueous bromine + aqueous sodium chloride

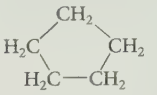
125. At which electrode in a voltaic cell does oxidation always occur? What is the charge on this electrode?

126. What would you observe when a length of nickel wire is immersed in an aqueous solution of silver nitrate?

127. For each pair of metals shown below, decide which metal is more readily reduced.

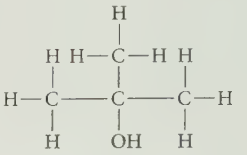
a. Cu, Mg **c.** Ag, Sn **e.** Ni, Cd
b. Cd, Ni **d.** Zn, Fe **f.** Al, Cu

***128.** Write a molecular structure for each compound.



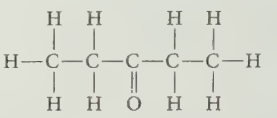
a. heptane **c.** 2-phenylbutane
b. 2-methyl-3-hexene **d.** 1,3-diethylbenzene

129. Name the next highest homolog of each of these compounds.



a. 1-butene **c.** pentane
b. cyclooctane **d.** nonane

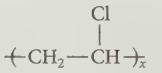
***130.** Give the IUPAC name for these compounds.



a.

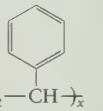
b.

c.



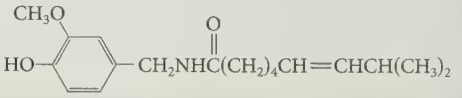
131. Write a molecular formula for each compound.

a. methyl acetate
b. 2-hydroxypropanoic acid



132. Name each polymer and state at least one of its uses.

a. $+CF_2—CF_2+_x$ **c.** $H+CH_2—CH_2+H$



b.

d.

133. Capsaicin, shown below, is the major contributor to the heat of chili peppers. Circle and name the functional groups in capsaicin.

Standardized Test Prep for Indiana

Tips for Success

Anticipating the Answer You can sometimes figure out the answer to a question before you look at the answer choices. Try to answer the question in your mind before you look at the answer choices. Then read the choices and choose the choice that agrees with the answer in your mind.

Select the choice that best answers each question or completes each statement.

1. What phrase best describes ATP?
   (A) energy producer
   (B) energy consumer
   (C) energy pump
   (D) energy transmitter

For Questions 2–5, match the category of organic compounds listed below that is most closely identified with each biological molecule.

I. monosaccharides
II. amino acids
III. fatty acids
IV. nucleotides

2. proteins
3. nucleic acids
4. lipids
5. carbohydrates

6. Which element is not found in amino acids?
   (A) phosphorus (C) oxygen
   (B) nitrogen (D) hydrogen

7. For any enzyme to function, the substrate must bind to the
   (A) product. (C) active site.
   (B) cofactor. (D) peptide.

Use the paragraph to answer Questions 8–10.
Because an amino acid contains both a carboxyl group and an amino group, it is amphoteric, that is, it can act as either an acid or a base. Crystalline amino acids have some properties—relatively high melting points and high water solubilities—that are more characteristic of ionic substances than of molecular substances.

8. Write an equation showing glycine acting as an acid in a reaction with water. (Glycine is the simplest amino acid. Its side chain is R = H.)
9. Write an equation showing glycine acting as a base in a reaction with water.
10. It is possible for glycine to undergo an internal Brønsted-Lowry acid-base neutralization reaction. Write the resulting structural formula. Explain how this reaction would account for the ionic properties of glycine.

For each question, there are two statements. Decide whether each statement is true or false. Then decide whether Statement II is a correct explanation for Statement I.

	Statement I		Statement II
11.	Lipids tend to be insoluble in water.	BECAUSE	Lipids have mainly nonpolar bonds.
12.	Starch and cellulose are both digestible by most organisms.	BECAUSE	Glucose is the monomer in both starch and cellulose.
13.	Many of the reactions in catabolism are oxidation reactions.	BECAUSE	Oxidation reactions tend to be energy-producing reactions.
14.	The sequence of bases in DNA contains the code for making proteins.	BECAUSE	Each pair of bases in DNA codes for a specific amino acid.

Materials List

For the Student

Small-Scale Lab, p 887
- ruler
- penny
- graph paper

Quick Lab, p 896
- flashlight
- strips of duct tape
- scissors
- poster board
- white (50 cm × 50 cm) meter ruler or tape measure flat surface long enough to hold the meter ruler
- graph paper
- light sensor (optional)

For the Teacher

Teacher Demo, p 878
- photographic film
- radiation source
- key

Class Activity, p 885
- reference materials and Internet access
- miscellaneous materials for models

Teacher Demo, p 889
- wooden matchsticks

Teacher Demo, p 895
- Geiger counter

Additional Digital Resources

Online Student Edition
Online Teacher's Edition

What's Online

CHEM TUTOR Students access a guided, step-by-step tutorial for using half-lives in calculations.

PROBLEM SETS Students can practice key problem-solving skills in an online problem set.

MATH HELP Identify the students that struggle with math by assigning an online math skills diagnostic test. These students can then improve and practice math skills using the MathXL tutorial system.

VIRTUAL LAB Students go on an animated virtual lab tour in which radioactive decay is studied in a simulated laboratory environment.

KINETIC ART Students watch animations of selected figures from the chapter and then answer questions that check for understanding.

CONCEPTS IN ACTION Students watch an overview of a key chapter concept using real-world contexts and concrete examples and analogies. Each activity includes an interactive animation followed by analysis questions.

IN ACADEMIC STANDARDS for SCIENCE

Nature of Science

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.
- Clearly communicate their ideas and results of investigations verbally and in written form using tables, graphs, diagrams, and photographs.

Standard 2: Atomic Structure and the Periodic Table

C.2.7 Compare and contrast nuclear reactions. For nuclear reactions, describe how the fusion and fission processes transform elements present before the reaction into elements present after the reaction.

Also covered C.2.8

Focus on ELL

1 CONTENT AND LANGUAGE Write the words *nucleus* and *nuclear* on the board. Ask students to recall the definition of *nucleus* based on what they learned in Chapter 4. Explain that this chapter is about the changes that can occur during nuclear reactions.

BEGINNING: LOW/HIGH Draw a diagram of a simple atom and identify the nucleus, and the subatomic particles. Use simple words and the diagram to illustrate that the composition of an atom's nucleus can change.

INTERMEDIATE: LOW/HIGH Create visual representations of the words *nuclear, radiation, transformations, fission,* and *fusion.* Then orally explain how the words are related.

ADVANCED: LOW/HIGH Read the lesson titles aloud. Have students predict how nuclear chemistry is related to each of these topics.

BIGIDEA

ELECTRONS AND THE STRUCTURE OF ATOMS

Essential Questions:

1. *What happens when an unstable nucleus decays?*
2. *How is the structure of atoms altered during fission and fusion?*
3. *How does nuclear chemistry affect your life?*

CHEMYSTERY

An Ice-Age Baby

In 2007, a reindeer herder in north-central Russia thought he spotted the frozen remains of a reindeer. What he found was a perfectly preserved baby wooly mammoth about the size of a large dog. The only thing missing was its shaggy coat. Scientists named the mammoth Lyuba, which means "love" in Russian.

Wooly mammoths are an extinct species related to modern elephants. These large mammals had curly tusks and long hair. They lived on Earth from about 1.8 million years ago until about 11,500 years ago. How do scientists know when Lyuba lived and died?

▶ Connect to the BIGIDEA As you read about nuclear reactions, think about which type of reaction could be used to find the age of a wooly mammoth fossil.

INDIANA'S ACADEMIC STANDARDS FOR SCIENCE

Atomic Structure and the Periodic Table C.2.7, C.2.8. See lessons for details.

Introduce the Chapter

IDENTIFYING MISCONCEPTIONS Students may have trouble understanding that radioactive decay takes place at a constant rate, or that the time period during which the decay occurs can be divided into intervals called half-lives. Use the activity to simulate the decay process.

Activity *You will need 40 jelly beans and 40 seeds or two other small, identical objects. Place each set of objects on a paper plate.* Have a volunteer replace 20 of the jelly beans with 20 seeds, one at a time. Time the process and say that this time is the half-life for jelly beans because half the original number of beans were replaced. Ask a second volunteer to show what will happen during the next half-life. *(10 beans will be replaced, which is half of the remaining 20)*

UbD

Understanding By Design

Students are building toward understanding nuclear chemistry using the structure of atomic nuclei.

PERFORMANCE GOALS At the end of Chapter 25, students will be able to answer the essential questions by applying their knowledge of nuclear chemistry. Students will also be able to calculate how much of an isotope will remain after a given number of half-lives.

ESSENTIAL QUESTIONS Read the essential questions aloud. **Ask** How may an atom make itself more chemically stable? *(It gains, loses, or shares valence electrons to form a stable octet.)* **Ask** How might an unstable atomic nucleus change to become stable? *(The numbers of protons and/or neutrons change.)* **Ask** How might these changes be related to fusion and fission? *(Fusion and fission are processes that involve unstable nuclei.)*

BIGIDEA Use the photo of the nuclear submarine to help students connect to the concepts they will learn in this chapter. Activate prior knowledge by asking students if they know any ways that nuclear energy is used. Point out that nuclear energy, like other forms of energy, can be transformed into different forms of energy. The submarine in the photo transforms the energy generated by nuclear reactions into both electrical and mechanical energy. Tell students that in this chapter they will study how the structure of atoms is related to nuclear reactions.

CHEMYSTERY Have students read over the CHEMystery. Connect the CHEMystery to the Big Idea of Electrons and the Structure of Atoms by explaining that nuclear reactions change an atom's structure. Have students predict how scientists know when the baby wooly mammoth lived and died.

LESSON 25.1

Key Objectives

25.1.1 EXPLAIN how an unstable nucleus releases energy.

25.1.2 DESCRIBE the three main types of nuclear radiation.

Additional Resources

Reading and Study Workbook, Lesson 25.1

Available Online or on Digital Media:

- Teaching Resources, Lesson 25.1 Review

PearsonChem.com

Engage

CHEMISTRY & YOU Have students study the photograph and read the text that opens the lesson. **Ask** When you have an X-ray taken at the dental office, why does the technician drape a heavy shield over your body? *(the shield is a radiation barrier)* Explain that these X-ray shields are typically comprised of lead, which is why they are so heavy. Tell students that because of its high density and high atomic number, lead it is effective at stopping radiation from X-rays.

Activate Prior Knowledge

Display the electromagnetic spectrum, given in Figure 5.8. Remind students that in Chapter 5 they learned that the electromagnetic spectrum consists of radiation over a broad range of wavelengths. Point out that electromagnetic radiation includes radio waves, microwaves, infrared waves, visible light, ultraviolet waves, X-rays, and gamma rays.

IN ACADEMIC STANDARDS for SCIENCE

C.2.7 Compare and contrast nuclear reactions with chemical reactions. For nuclear reactions, describe how the fusion and fission processes transform elements present before the reaction into elements present after the reaction.

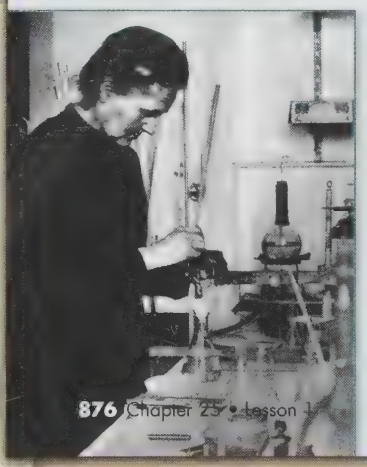
25.1 Nuclear Radiation

C.2.7 Compare and contrast nuclear reactions with chemical reactions.

CHEMISTRY & YOU

Q: *What makes some types of radiation more dangerous than other types?* Atoms emit electromagnetic radiation when an electron moves from a higher energy level to a lower energy level. Most electromagnetic radiation, such as visible light, has low energy and is not dangerous. X-rays are an exception. Lengthy or frequent exposure to X-rays can damage cells in your body. This lesson will explain why exposure is also a concern with nuclear radiation.

Key Questions



How do nuclear reactions differ from chemical reactions?

What are three types of nuclear radiation?

Vocabulary

- radioactvity
- nuclear radiation
- radioisotope
- alpha particle
- beta particle
- gamma ray

Figure 25.1 Marie Curie
Marie Curie and her husband Pierre shared the 1903 Nobel Prize in physics with Becquerel for their pioneering work on radioactivity.

Radioactivity

How do nuclear reactions differ from chemical reactions?

In 1896, the French chemist Antoine Henri Becquerel made an accidental discovery. He was studying the ability of uranium salts that had been exposed to sunlight to fog photographic film plates. During bad weather, when Becquerel could not expose a sample to sunlight, he left the sample on top of the photographic plate. When he developed the plate, he discovered that the uranium salt still fogged the film. At the time, two of Becquerel's associates were Marie and Pierre Curie. The Curies were able to show that rays emitted by uranium atoms caused the film to fog. Marie Curie is shown in Figure 25.1. She used the term **radioactivity** to refer to the spontaneous emission of rays or particles from certain elements, such as uranium. The rays and particles emitted from a radioactive source are called **nuclear radiation.**

Radioactivity, which is also called radioactive decay, is an example of a nuclear reaction. In both chemical reactions and nuclear reactions, atoms become more stable. The word *stable* means "constant" or "not likely to change." In a chemical reaction, atoms tend to attain a more stable electron configuration by transferring or sharing electrons. Nuclear reactions begin with unstable isotopes, or **radioisotopes.** Atoms of these isotopes become more stable when changes occur in their nuclei. The changes are always accompanied by the emission of large amounts of energy. **Unlike chemical reactions, nuclear reactions are not affected by changes in temperature, pressure, or the presence of catalysts. Also, nuclear reactions of a given radioisotope cannot be slowed down, speeded up, or stopped.**

Radioactive decay is a spontaneous process that does not require an input of energy. If the product of a nuclear reaction is unstable, it will decay too. The process continues until unstable isotopes of one element are changed, or transformed, into stable isotopes of a different element. These stable isotopes are not radioactive.

Focus on ELL

1 CONTENT AND LANGUAGE Write *alpha*, *beta*, and *gamma* on the board and explain that these words are the names of Greek letters. Then, write the letters beside their names. Note that scientists often use Greek letters as symbols to represent sub-categories of substances.

2 FRONTLOAD THE LESSON Write the symbols for the isotopes of carbon-12 and carbon-14 on the board, and review what the numbers in each symbol represent. Then preview the equations in the lesson, and ask students how they differ from chemical equations.

3 COMPREHENSIBLE INPUT Explain the use of the terms *parent* and *daughter* with respect to nuclei. Then write the equation for the alpha decay of uranium-238 on the board, replacing the alpha particle with a question mark. Walk students through the steps of balancing a nuclear equation. Then have students examine Table 25.1 to locate a particle that will balance the equation.

Table 25.1

Characteristics of Some Types of Radiation

Type	Consists of	Symbol	Charge	Mass (amu)	Common source	Penetrating power
Alpha radiation	Alpha particles (helium nuclei)	α, $^{4}_{2}He$	2+	4	Radium-226	Low (0.05 mm body tissue)
Beta radiation	Beta particles (electrons)	β, $^{0}_{-1}e$	1–	1/1837	Carbon-14	Moderate (4 mm body tissue)
Gamma radiation	High-energy electromagnetic radiation	γ	0	0	Cobalt-60	Very high (penetrates body easily)

Types of Radiation

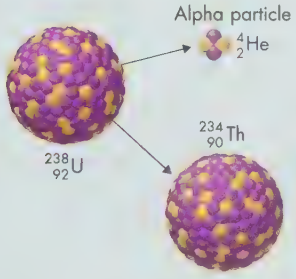
What are three types of nuclear radiation?

Radiation is emitted during radioactive decay. **Three types of nuclear radiation are alpha radiation, beta radiation, and gamma radiation.** Table 25.1 summarizes the characteristics of these three types of radiation.

Alpha Radiation Some radioactive sources emit helium nuclei, which are also called alpha particles. Each **alpha particle** contains two protons and two neutrons and has a double positive charge. In nuclear equations, an alpha particle is written $^{4}_{2}He$ or α. The electric charge symbol is usually omitted.

The radioisotope uranium-238 emits alpha radiation and is transformed into another radioisotope, thorium-234. Figure 25.2 illustrates this process.

$$\underset{\text{Uranium-238}}{^{238}_{92}U} \xrightarrow[\text{decay}]{\text{Radioactive}} \underset{\text{Thorium-234}}{^{234}_{90}Th} + \underset{\text{Alpha particle}}{^{4}_{2}He\ (\alpha \text{ emission})}$$



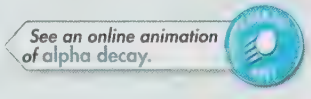


Figure 25.2 Alpha Decay
Uranium-238 decays and forms thorium-234. The radiation emitted is an alpha particle.
Interpret Diagrams
Describe the structure of an alpha particle?

When an atom loses an alpha particle, the atomic number of the product is lower by two and its mass number is lower by four. In a balanced nuclear equation, the sum of the mass numbers (superscripts) on the right must equal the sum on the left. The same is true for the atomic numbers (subscripts).

Because of their large mass and charge, alpha particles do not travel very far and are not very penetrating. A sheet of paper or the surface of your skin can stop them. But radioisotopes that emit alpha particles can cause harm when ingested. Once inside the body, the particles don't have to travel far to penetrate soft tissue.

Professional Development Note — Nuclear Decay

Nuclear decay, unlike chemical reactions, is unaffected by temperature, pressure, or the presence of catalysts. Spontaneous nuclear decay cannot be slowed down, speeded up, or stopped. Nuclear decay illustrates the interconnected nature of matter and energy—matter is related to energy according to the equation $E = mc^2$, where c is a constant equal to the speed of light. The energy produced during nuclear decay can be released as electromagnetic radiation, such as gamma rays, or as kinetic energy, which is carried by particles, such as alpha particles.

Foundations for Reading

BUILD VOCABULARY Have students look up the meanings of the first three vocabulary terms. Then, have them infer the meaning of the prefix used in all three terms. Students should infer that the prefix *radio-* means "to send out in all directions."

READING STRATEGY Have students use context clues to infer the definition of *decay,* as it refers to radioactivity. Inferences should include that *decay* means "breaking down into smaller parts."

Explain

Radioactivity

START A CONVERSATION **Ask** What particles in an atom are involved in chemical reactions? *(valence electrons)* **Ask** How does a chemical reaction compare to a nuclear reaction? *(Chemical reactions involve the transfer or sharing of electrons; the nuclei remain unchanged. Nuclear reactions involve changes in the nuclei of atoms.)*

Misconception Alert

Students may think that the radioisotopes of an element are chemically different from other isotopes of that element. Point out that chemical reactivity depends on the electron structure of an atom, not its nuclear structure.

Types of Radiation

APPLY CONCEPTS Write the following statement on the board: *Nuclear chemistry is the study of changes in matter that originate in atomic nuclei.* **Ask** What types of nuclear radiation exist, and how harmful are they? *(The three most common types of radiation emitted by unstable nuclei are alpha (α), beta (β), and gamma (γ) radiation. Although all forms of nuclear radiation are somewhat harmful, gamma rays are particularly dangerous because they penetrate body tissues.)*

USE VISUALS Have students examine Table 25.1. Encourage them to memorize the names and symbols used to represent each type of radiation. Point out the differences in charge and mass. Students may wish to recreate Table 25.1 on an index card and use the information to help them write and balance nuclear equations. Point out the relative penetrating power of each type of radiation.

Answers

Explore

Types of Radiation

Teacher Demo

PURPOSE Students will observe the effects of radiation on photographic film.

MATERIALS photographic film, radiation source, key

SAFETY Use only safely packaged radiation sources. Do not directly touch any radioactive material.

PROCEDURE Explain that some types of radiation can reduce silver in photographic film. This property led to the discovery of radioactivity by Becquerel. Place a metal key on top of unexposed photographic film that has been wrapped in black paper. Place a radiation source on top of the key. After one week, develop the film.

EXPECTED OUTCOME The area of the film that was beneath the key is unexposed, unlike the rest of the film. Remind students of this demonstration when they study film badges in Lesson 25.4.

CHEMISTRY & YOU The amount of energy determines the penetrating power of electromagnetic radiation.

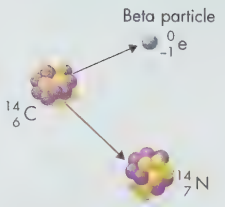

Figure 25.3 Beta Decay
When a carbon-14 atom decays, the products are nitrogen-14 and a beta particle.

Beta Radiation An electron resulting from the breaking apart of a neutron in an atom is called a **beta particle.** The neutron breaks apart into a proton, which remains in the nucleus, and a fast-moving electron, which is released.

$$^{1}_{0}n \longrightarrow {}^{1}_{1}p + {}^{0}_{-1}e$$

Neutron → Proton + Electron (beta particle)

The symbol for the electron has a subscript of –1 and a superscript of 0. The –1 represents the charge on the electron. The 0 represents the extremely small mass of the electron compared to the mass of a proton.

Carbon-14 is a radioisotope. It emits a beta particle as it decays and forms nitrogen-14. Figure 25.3 illustrates this reaction.

$$^{14}_{6}C \longrightarrow {}^{14}_{7}N + {}^{0}_{-1}e\ (\beta\ \text{emission})$$

Carbon-14 (radioactive) → Nitrogen-14 (stable) + Beta particle

The nitrogen-14 atom has the same mass number as carbon-14, but its atomic number has increased by 1. It contains an additional proton and one fewer neutron. The nuclear equation is balanced.

A beta particle has less charge than an alpha particle and much less mass than an alpha particle. Thus, beta particles are more penetrating than alpha particles. Beta particles can pass through paper but are stopped by aluminum foil or thin pieces of wood. Because of their opposite charges, alpha and beta radiation can be separated by an electric field, as shown in Figure 25.4.

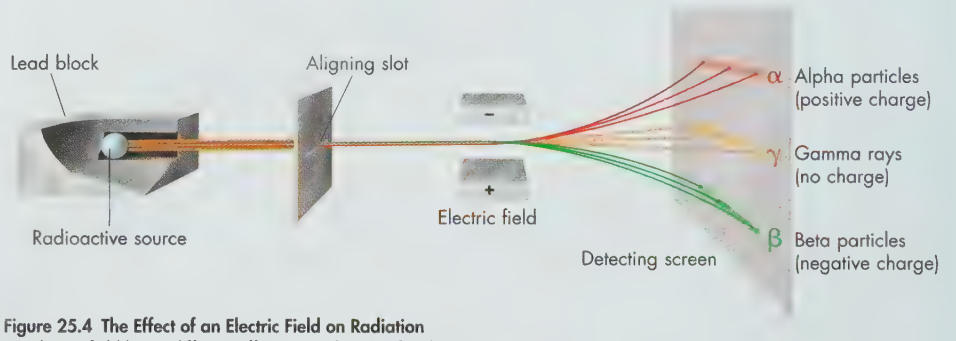

Figure 25.4 The Effect of an Electric Field on Radiation
An electric field has a different effect on each type of radiation. Alpha and beta particles move in opposite directions. Alpha particles move toward the negative plate and beta particles move toward the positive plate. Gamma rays are not deflected as they pass between the plates.
Applying Concepts *Why are gamma rays not deflected?*

UbD Check for Understanding

What are three types of nuclear radiation?

Have students list three types of nuclear radiation and explain how they differ from one another. *(Three types of nuclear radiation are alpha particles, beta particles, and gamma rays. Alpha particles are helium nuclei, which consist of two protons and four protons and have a charge of +2. Beta particles are electrons that are emitted from the nucleus when a neutron splits into a proton and an electron. Gamma rays are high-energy photons that are often emitted when alpha or beta particles are emitted, but have no effect on the mass number or atomic number of nuclei.)*

ADJUST INSTRUCTION Have students review Table 25.1 and examine the nuclear reaction examples shown in the Types of Radiation section. Then allow students an opportunity to revise their answers.

878 Chapter 25 • Lesson 1

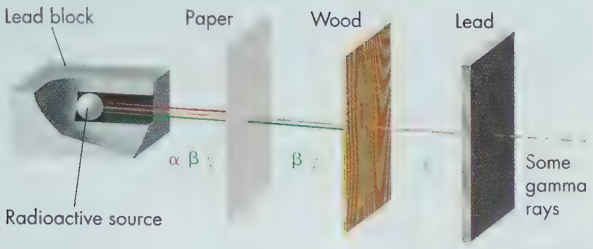

Figure 25.5 Relative Penetrating Power of Nuclear Radiation
Because of their large mass and charge, alpha particles (red) are the least penetrating of the three main types of nuclear radiation. Gamma rays (yellow) have no mass or charge and are the most penetrating.
Infer ***How penetrating are beta particles (green) compared to alpha particles and gamma rays?***

Gamma Radiation A high-energy photon emitted by a radioisotope is called a **gamma ray.** The high-energy photons are a form of electromagnetic radiation. Nuclei often emit gamma rays along with alpha or beta particles during radioactive decay. The following examples demonstrate this process.

$$^{230}_{90}\text{Th} \longrightarrow {}^{226}_{88}\text{Ra} + {}^{4}_{2}\text{He} + \gamma$$

Thorium-230 — Radium-226 — Alpha particle — Gamma ray

$$^{234}_{90}\text{Th} \longrightarrow {}^{234}_{91}\text{Pa} + {}^{0}_{-1}\text{e} + \gamma$$

Thorium-234 — Protactinium-234 — Beta particle — Gamma ray

Gamma rays have no mass and no electrical charge. So the emission of gamma radiation does not alter the atomic number or mass number of an atom. Because gamma rays are extremely penetrating, they can be very dangerous. For example, gamma rays pass easily through paper, wood, and the human body. They can be stopped, although not completely, by several meters of concrete or several centimeters of lead, as shown in Figure 25.5.

CHEMISTRY & YOU

Q: *Gamma rays can be dangerous because of their penetrating power. What property determines the relative penetrating power of electromagnetic radiation?*

25.1 LessonCheck

1. **Compare** What factors do not affect nuclear reactions, but do affect chemical reactions?
2. **Describe** Briefly describe the three main types of nuclear radiation.
3. **Identify** What part of an atom undergoes change during radioactive decay?
4. **Compare and Contrast** How is the atomic number of a nucleus changed by alpha decay? By beta decay? By gamma decay?
5. **Describe** What two items must be equal for a nuclear equation to be balanced?
6. **Relate Cause and Effect** How does alpha decay affect the mass number of a nucleus? How does beta decay affect the mass number?
7. **Identify** Which of the three types of radiation described in this lesson is the most penetrating, and why?
8. **Predict** When polonium-210 decays by alpha radiation, what isotope is formed?

Lesson Check Answers

1. temperature, pressure, or the presence of catalysts
2. Alpha particles are helium nuclei with a positive charge. Beta particles are fast-moving electrons. Gamma rays are high-energy photons.
3. The nucleus undergoes change.
4. In alpha decay, the atomic number decreases by two. In beta decay, the atomic number increases by one. With gamma rays, the atomic number does not change.
5. The sum of the mass numbers and the sum of the atomic numbers on the right side of the equation must equal the corresponding sums on the left side of the equation.
6. In alpha decay, the mass number decreases by four. In beta decay, the mass number does not change.
7. Gamma radiation, because it has the highest energy
8. lead-206

Evaluate

Informal Assessment

Write several partial equations for nuclear decay involving alpha and beta particles using only the parent and daughter nuclei. Have students compare the two nuclei in each equation to identify the type of particle emitted and justify their conclusions.
Ask What other type of emission is possible during nuclear decay? *(gamma rays)* Then have students complete the 25.1 Lesson Check.

Reteach

Remind students that when writing a nuclear equation, the sums of the mass numbers and atomic numbers of the reactants must equal the sums of the mass numbers and atomic numbers of the products. Students should check their equations by comparing the sums of the superscripts and subscripts on each side of the equation.

Answers

FIGURE 25.4 Gamma rays are not deflected by the electric field because they have no charge.
FIGURE 25.5 Beta particles are more penetrating than alpha particles but less penetrating than gamma rays.

LESSON 25.2

Key Objectives

- **25.2.1 DESCRIBE** the type of decay a radioisotope undergoes.
- **25.2.2 SOLVE** problems that involve half-life.
- **25.2.3 IDENTIFY** two ways transmutations can occur.

Engage

CHEMISTRY & YOU Have students read the opening text. Tell students that radon-222 emits alpha radiation—the least harmful of the three main types of nuclear radiation. **Ask** So why does the level of radon need to be monitored? *(Because radon is a gas, it can be inhaled. Thus, the radiation that it emits can penetrate body tissues.)*

Build Background

Have students consider how stable a nucleus would be if it contained only protons. **Ask** In terms of stability, what purpose might the neutrons serve in an atom? *(The neutrons separate the positive charges in a nucleus and limit the repulsive forces between protons.)*

IN ACADEMIC STANDARDS for SCIENCE

C.2.7 Compare and contrast nuclear reactions with chemical reactions. For nuclear reactions, describe how the fusion and fission processes transform elements present before the reaction into elements present after the reaction.

C.2.8 Understand that the radioactive decay process is random for any given atom, but that this property leads to a predictable and measurable exponential decay of a sample of radioactive material. Calculate the initial amount, the fraction remaining, or the half-life of a radioactive sample given two of the three variables.

25.2 Nuclear Transformations

C.2.7 Compare and contrast nuclear reactions with chemical reactions; C.2.8 Radioactive decay

CHEMISTRY & YOU

Q: *What is the source of radon in homes?* All the isotopes of radon gas are unstable and emit radiation. Inhaled radon is the second leading cause of lung cancer in the United States. Radon may accumulate in a basement that is not well ventilated. Because radon is a colorless, odorless gas, people often do not know that they are being exposed to high levels of radon. Test kits are available to measure the levels of radon in a building. In this lesson, you will study the decay series that produces this hazardous gas.

Key Questions

- ***What determines the type of decay a radioisotope undergoes?***
- ***How much of a radioactive sample remains after each half-life?***
- ***What are two ways in which transmutation can occur?***

Vocabulary

- nuclear force
- band of stability
- positron
- half-life
- transmutation
- transuranium elements

Nuclear Stability and Decay

What determines the type of decay a radioisotope undergoes?

All atomic nuclei, except those of hydrogen atoms, consist of neutrons and two or more protons. If a force did not hold these subatomic particles together, the like-charged protons would repel one another and fly apart. The **nuclear force** is an attractive force that acts between *all* nuclear particles that are extremely close together, such as protons and neutrons in a nucleus. At these short distances, the nuclear force dominates over electromagnetic repulsions and holds the nucleus together.

More than 1,500 different nuclei are known. Only 264 of the known nuclei are stable and do not decay. The rest are unstable and will change over time. The stability of a nucleus depends on the ratio of neutrons to protons. Figure 25.6 shows a graph of the number of neutrons vs. the number of protons for all known stable nuclei. The region of the graph in which these points are located is called the **band of stability.** For elements of low atomic number (below about 20), this ratio is about 1. Above atomic number 20, stable nuclei have more neutrons than protons.

A nucleus may be unstable and undergo spontaneous decay for different reasons. **The neutron-to-proton ratio in a radioisotope determines the type of decay that occurs.** Some nuclei are unstable because they have too many neutrons relative to the number of protons. When one of these nuclei decays, a neutron emits a beta particle (fast-moving electron) from the nucleus. A neutron that emits an electron becomes a proton.

$$^{1}_{0}n \longrightarrow {}^{1}_{1}p + {}^{0}_{1}e$$

This process is known as beta emission. It increases the number of protons while decreasing the number of neutrons. Radioisotopes that undergo beta emission include the following.

$$^{66}_{29}Cu \longrightarrow {}^{66}_{30}Zn + {}^{0}_{-1}e$$

$$^{14}_{6}C \longrightarrow {}^{14}_{7}N + {}^{0}_{-1}e$$

Focus on ELL

1 CONTENT AND LANGUAGE Have students name things that may be stable or unstable in everyday life. Then have them describe how an atom can be unstable. Discuss the common use of the word *decay* to mean "break down" or "rot." Use fruit as an example to explain that decaying or rotting is a process that evolves over time.

2 FRONTLOAD THE LESSON Have students consider cell division as an example of exponential change. Point out that in cell division, the number of existing cells double each time the group of cells completes a cell cycle: two cells become four, four become eight, and so on. Tell students that radioactive decay is also exponential.

3 COMPREHENSIBLE INPUT When discussing Figure 25.8, project the figure on the board alongside an image of the periodic table. Help students trace the decay series on the periodic table to reinforce the concept that radioactive decay of one element's isotope results in the formation of another element's isotope.

Interpret Graphs

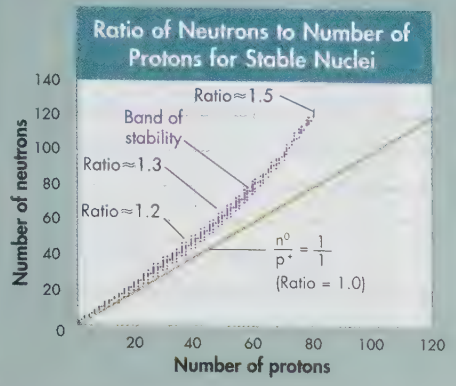

Figure 25.6 A plot of neutrons vs. protons for all stable nuclei forms a pattern called the band of stability, which is shown in purple. The green line shows what the pattern would be if the ratio were 1 for every nucleus.

a. Identify What does each dot represent?

b. Read Graphs What is the ratio of neutrons to protons for tin (Sn, atomic number = 50)?

c. Describe How does the neutron-to-proton ratio change as the number of protons increases in stable nuclei?

Other nuclei are unstable because they have too few neutrons relative to the number of protons. These nuclei increase their stability by converting a proton to a neutron. An electron is captured by a nucleus during this process, which is called electron capture. Here are two examples of electron capture.

$$^{59}_{28}\text{Ni} + {}^{0}_{-1}\text{e} \longrightarrow {}^{59}_{27}\text{Co}$$

$$^{37}_{18}\text{Ar} + {}^{0}_{-1}\text{e} \longrightarrow {}^{37}_{17}\text{Cl}$$

A **positron** is a particle with the mass of an electron but a positive charge. Its symbol is ${}^{0}_{+1}\text{e}$. During positron emission, a proton changes to a neutron, just as in electron capture. Here are two examples of positron emission.

$$^{8}_{5}\text{B} \longrightarrow {}^{8}_{4}\text{Be} + {}^{0}_{+1}\text{e}$$

$$^{15}_{8}\text{O} \longrightarrow {}^{15}_{7}\text{N} + {}^{0}_{+1}\text{e}$$

When a proton is converted to a neutron, the atomic number decreases by 1 and the number of neutrons increases by 1.

All nuclei that have an atomic number greater than 83 are radioactive. These nuclei have both too many neutrons and too many protons to be stable. Therefore, they undergo radioactive decay. Most of them emit alpha particles. Alpha emission increases the neutron-to-proton ratio, which tends to increase the stability of the nucleus. In alpha emission the mass number decreases by four and the atomic number decreases by two.

$$^{226}_{88}\text{Ra} \longrightarrow {}^{222}_{86}\text{Rn} + {}^{4}_{2}\text{He}$$

$$^{232}_{90}\text{Th} \longrightarrow {}^{228}_{88}\text{Ra} + {}^{4}_{2}\text{He}$$

Recall that conservation of mass is an important property of chemical reactions. In contrast, mass is not conserved during nuclear reactions. An extremely small quantity of mass is converted into the energy released during radioactive decay.

Foundations for Reading

BUILD VOCABULARY Have students look up the definitions of the vocabulary words. Then, have them paraphrase each definition.

READING STRATEGY As students read through the section, have them look for and list examples of cause and effect relationships. For example, *nuclei are unstable because their neutron-to-proton ratio is greater than one.*

Explain

Nuclear Stability and Decay

CRITICAL THINKING Explain that, for each element, there exists only a small range of neutron-to-proton ratios that produce stable nuclei. If a nucleus does not reflect a stable ratio, it spontaneously decays until a stable ratio of neutrons to protons results.

Extend

Explain that beta decay can result in either the emission of an electron (a β^- particle) or a positron (a β^+ particle). Write the partial equation for the decay of chlorine-32 into sulfur-32 on the board. **Ask** Which kind of particle would need to be emitted to balance the equation? *(a positron)* Explain that during positron emission, a proton is converted into a neutron. **Ask** What kind of unstable nuclei would be likely to emit positrons? *(one with too many protons for the number of neutrons)*

MAKE A CONNECTION Explain that emission of a positron also results in a neutrino, while electron emission is accompanied by an anti-neutrino. Neutrinos and anti-neutrinos have no charge and virtually no mass. Their emissions are not included in the student text because they are not chemically significant and do not react significantly with matter. However, their presence satisfies the laws of energy-mass conservation and momentum conservation.

UbD Check for Understanding

BIG IDEA ELECTRONS AND THE STRUCTURE OF ATOMS Assess students' knowledge about nuclear stability and decay by asking them to complete the following analogy:

The structural stability that results from a proper ratio of mortar to bricks in a building is like the nuclear stability that results from a proper ratio of _____ to _____ in an atom.

ADJUST INSTRUCTION If students are having trouble answering, have them re-read the first three paragraphs of Nuclear Stability and Decay section for review. Then ask them to complete the analogy again.

Answers

FIGURE 25.6

a. Each dot represents a stable nucleus.

b. 1.3

c. The ratio increases.

Explain

Half-Life

INTERPRET GRAPHS Have students examine the graph in Figure 25.7. Discuss the role neutrons play in stabilizing the nuclei of atoms. Point out that nearly 85% of all known nuclei are unstable and the distribution of stable and unstable isotopes is not even. Because neutrons help bind protons together in the nucleus, the ratio of protons to neutrons is a major factor in determining stability. Encourage students to research the strong nuclear force, the force of attraction that holds nucleons together in a stable nucleus.

CRITICAL THINKING

Direct students' attention to Figure 25.7. **Ask** Will the curve on the graph ever reach zero? *(Sample answer: Theoretically, it could reach zero if the last radioactive atom in a sample decays. However, it would not be practical to graph the number of half-lives this event would take, and the amount of radioisotope present would be non-detectable.)* For advanced math students, **Ask** Which mathematical concepts can be used to explain the behavior of the graph? *(Sample answers: inverse function, limits, infinity)*

USE VISUALS Refer students to Table 25.2 and have them note the range of half-life values. Remind students that these values do not indicate how long a given atom of an isotope will exist, but only how long it takes for half of the atoms in a sample to undergo radioactive decay.

CHEMISTRY & YOU One intermediate in the decay series for U-238 is Rn-222. This gas can seep into buildings and collect if a building is not well ventilated.

Interpret Graphs

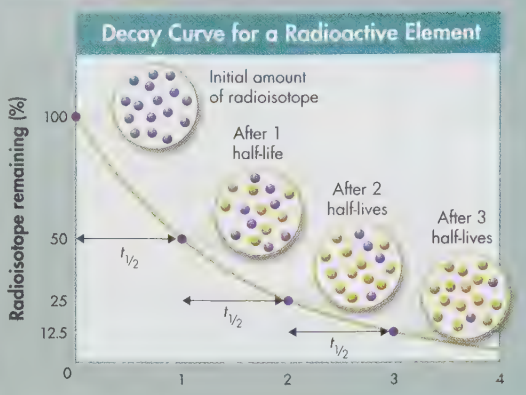

Figure 25.7 This decay curve shows that during each half-life, half of the radioactive atoms decay into atoms of another element.

a. Read Graphs What percent of the original atoms remains after one half-life? After two half-lives?

b. Read Graphs How many half-lives does it take for 12.5% of the radioisotope to remain?

c. Apply Concepts Explain why this graph can apply to all radioisotopes.

CHEMISTRY & YOU

Q: *Uranium compounds are found in rocks and in soils that form from these rocks. How can these uranium compounds lead to a build up of radon in homes and other buildings?*

Half-Life

How much of a radioactive sample remains after each half-life?

Every radioisotope has a characteristic rate of decay, which is measured by its half-life. A half-life ($t_{\frac{1}{2}}$) is the time required for one-half of the nuclei in a radioisotope sample to decay to products, as shown in Figure 25.7. **After each half-life, half of the original radioactive atoms have decayed into atoms of a new element.**

Comparing Half-Lives Half-lives can be as short as a second or as long as billions of years. Table 25.2 shows the half-lives of some radioisotopes that occur in nature. Scientists use the half-lives of some long-term radioisotopes to determine the age of ancient objects. Many artificially produced radioisotopes have short half-lives, which makes them useful in nuclear medicine. Short-lived isotopes are not a long-term radiation hazard for patients.

Table 25.2

Half-Lives of Some Naturally Occurring Radioisotopes

Isotope	Half-life	Radiation emitted
Carbon-14	5.73×10^3 years	β
Potassium-40	1.25×10^9 years	β, γ
Radon-222	3.8 days	α
Radium-226	1.6×10^3 years	α, γ
Thorium-234	24.1 days	β, γ
Uranium-235	7.0×10^8 years	α, γ
Uranium-238	4.5×10^9 years	α

Differentiated Instruction

LPR LESS PROFICIENT READERS Have students who struggle with reading comprehension draw inferences from tables and numbers. For example, have students compare and contrast the change in radioactivity levels over time for samples of the isotopes potassium-40 and thorium-234. Using Table 25.2, they should be able to infer that the radiation emitted by a sample of K-40 would diminish much less rapidly than the radiation from a sample of Th-234 because of the much longer half-life of K-40.

L1 STRUGGLING STUDENTS To reinforce the concept of half-life, have students consider a $1000 prize with the following condition: Half of the remainder of the prize must be spent each month. **Ask** How many months would pass before only $1 was left? *(10 months)*

L3 ADVANCED STUDENTS Have students plot a decay curve for one of the elements in Table 25.2. Students should use an initial amount of 100 g of radioisotope, and plot change in concentration over time.

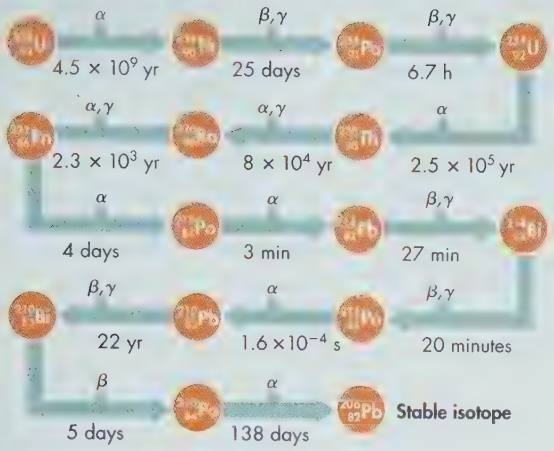

Figure 25.8 Decay Series of U-238 Uranium-238 decays through a series of radioactive intermediates, including radon (Rn) gas.
Interpret Diagrams *What is the stable end product of this series?*

One isotope that has a long half-life is uranium-238. It decays through a complex series of unstable isotopes to the stable isotope lead-206. Figure 25.8 summarizes this process. The age of uranium-containing minerals can be estimated by measuring the ratio of uranium-238 to lead-206. Because the half-life of uranium-238 is 4.5×10^9 years, it is possible to use its half-life to date rocks as old as the solar system.

Radiocarbon Dating Scientists often find the age of an object that was once part of a living system by measuring the amount of carbon-14 ($^{14}_{6}C$) it contains. Carbon-14 has a half-life of 5730 years. Most of Earth's carbon, however, consists of the more stable isotopes $^{12}_{6}C$ and $^{13}_{6}C$. The ratio of $^{14}_{6}C$ to the other carbon isotopes in the environment is fairly constant because high-energy cosmic rays from space constantly produce $^{14}_{6}C$ in carbon dioxide in the upper atmosphere.

Go online to learn more about radiocarbon dating.

Plants use carbon dioxide to produce carbon compounds, such as glucose. In those compounds, the ratio of carbon isotopes is the same as in the air. The same ratio is maintained as animals consume the plants, and other animals. Thus, the ratio of carbon-14 to other carbon isotopes is constant during an organism's lifetime. When an organism dies, it stops exchanging carbon with the environment and its radioactive $^{14}_{6}C$ atoms decay without being replaced. Therefore, the ratio of $^{14}_{6}C$ to stable carbon in the remains of an organism changes in a predictable way. Archaeologists can use this data to estimate when an organism died.

Exponential Decay Function You can use the following equation to calculate how much of an isotope will remain after a given number of half-lives.

$$A = A_0 \times \left(\frac{1}{2}\right)^n$$

In the formula, A stands for the amount remaining, A_0 for the initial amount, and n for the number of half-lives. The exponent n indicates how many times A_0 must be multiplied by $\frac{1}{2}$ to determine A. Table 25.3 shows examples in which $n = 1$ and $n = 2$.

Table 25.3
Decay of Initial Amount (A_0) of Radioisotope

Half-Life	Amount Remaining
0	$A_0 \times (\frac{1}{2})^0 = A_0$
1	$A_0 \times (\frac{1}{2})^1 = A_0 \times \frac{1}{2}$
2	$A_0 \times (\frac{1}{2})^2 = A_0 \times \frac{1}{2} \times \frac{1}{2}$

LIMITATIONS OF RADIOCARBON DATING There are two situations where radiocarbon dating is not an effective method of determining a fossil's age. First, not all fossils contain organic material, but are simply the imprint that remains after the organic material decomposed. Second, carbon-14 has a half-life of only 5730 years, meaning that very little of the isotope remains in items older than 60,000 years of age. In both cases, scientists can use radioisotopes of other elements to determine the fossil's age. This is usually accomplished by dating the rock in which the fossil is located.

MAKING CONNECTIONS Emphasize that the rate of disintegration of the nuclei of an isotope is unaffected by factors such as heat, pressure, or chemical reactions. Point out that the half-life for a particular radioactive isotope is unique to that isotope. Guide students to understand that no two isotopes have exactly the same half-life.

USE VISUALS Have students study Figure 25.8, which charts the radioactive decay of U-238. Explain that many radioisotopes go through a complex series of nuclear reactions before a stable product is formed.

Answers

INTERPRET GRAPHS

a. 50%; 25%
b. three half-lives
c. The percentage of a radioactive sample that remains after each half-life is the same for all isotopes.

FIGURE 25.8 lead-206

Explain

Sample Practice Problems

A. How much of a 0.74-mg sample of U-235 will remain after 2.8×10^9 years? *(4.6×10^2 mg)*

B. A 0.456-mg sample of hydrogen-3 was collected. After 24.52 years, 0.114 mg of the sample remains. What is the half-life of hydrogen-3? *(12.26 years)*

C. Strontium-90 is a beta emitter with a half-life of 29 years. What is the mass of strontium-90 in a 5.0-g sample of the isotope at the end of 87 years? *(0.63 g)*

CRITICAL THINKING Have students write down procedure steps they can follow to work problems involving whole-number half-lives.

Extend

Connect to MATHEMATICS

Challenge advanced math students to expand their procedures for solving half-life problems to include partial half-lives. Point out that if k is the rate of decay, then $t_{\frac{1}{2}} = \frac{\ln 2}{\lambda}$.

Challenge students to test their procedure by solving the following problem: A fossil was found to contain 60% of its original carbon-14. How old is the fossil?

($k = \ln 2/t_{1/2} = 0.693/5{,}730\ yr = 1.21 \times 10^{-4} yr^{-1}$;

$t = \frac{1}{k} \ln \frac{Ao}{At} = (1/1.21 \times 10^{-4} yr^{-1}) \times \ln(1/0.60) =$ 4,200 yr)

Sample Problem 25.1

Using Half-lives in Calculations

Carbon-14 emits beta radiation and decays with a half-life ($t_{\frac{1}{2}}$) of 5730 years. Assume you start with a mass of 2.00×10^{-12} g of carbon-14.

a. How long is three half-lives?

b. How many grams of the isotope remain at the end of three half-lives?

1 Analyze **List the knowns and the unknowns.**

To calculate the length of three half-lives, multiply the half-life by three. To find the mass of the radioisotope remaining, multiply the original mass by $\frac{1}{2}$ for each half-life that has elapsed.

KNOWNS	UNKNOWNS
$t_{\frac{1}{2}} = 5730$ years	3 half-lives = ? years
initial mass(A_0) 2.00×10^{-12} g	mass remaining = ? g
number of half-lives (n) = 3	

2 Calculate **Solve for the unknowns.**

Multiply the half-life of carbon-14 by the total number of half-lives.

a. $t_{\frac{1}{2}} \times n = 5730\ \text{years} \times 3 = 17{,}190\ \text{years}$

The initial mass of carbon-14 is reduced by one half for each half-life. So multiply by $\frac{1}{2}$ three times.

b. $\text{Remaining mass} = 2.00 \times 10^{-12}\ g \times \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2}$

$= 0.250 \times 10^{-12}\ g$

$= 2.50 \times 10^{-13}\ g$

You can get the same answer by using the equation for an exponential decay function.

c. $A = A_0\left(\frac{1}{2}\right)^n = (2.00 \times 10^{-12}\ g)\left(\frac{1}{2}\right)^3$

$= (2.00 \times 10^{-12}\ g)\left(\frac{1}{8}\right)$

$= 0.250 \times 10^{-12}\ g$

$= 2.50 \times 10^{-13}\ g$

3 Evaluate **Do the results make sense?** The mass of carbon-14 after three half-lives should be one-eighth of the original mass. If you divide 2.50×10^{-13} g by 2.00×10^{-12} g, you will get 12.5%, or $\frac{1}{8}$.

9. Manganese-56 is a beta emitter with a half-life of 2.6 h. What is the mass of manganese-56 in a 1.0-mg sample of the isotope at the end of 10.4 h?

10. Thorium-234 has a half-life of 24.1 days. Will all the thorium atoms in a sample decay in 48.2 days? Explain.

Foundations for Math

FRACTIONS AND EXPONENTS Students may be uncomfortable working with a fraction raised to an exponent in the exponential decay function. However, they may be comfortable with working with whole numbers raised to an exponent.

Remind students that the rules of exponents state that $\left(\frac{1}{2}\right)^n$ can be rewritten as $\frac{1^n}{2^n}$. Because 1 raised to any power is always 1, this equation can be further simplified to $\frac{1}{2^n}$. Demonstrate for students that if they know the value of 2^n, they can easily determine the value of $\left(\frac{1}{2}\right)^n$.

In **Sample Problem 25.1**, $n = 3$, so $\left(\frac{1}{2}\right)^n = \left(\frac{1}{2}\right)^3$. Because $2^3 = 8$, expanding this equation further gives $\frac{1^3}{2^3} = \frac{1}{2^3} = \frac{1}{8}$.

Transmutation Reactions

What are two ways in which transmutation can occur?

For thousands of years, alchemists tried to change lead into gold, an element which is more highly valued than lead. Despite much effort, they were not able to achieve their goal. What they wanted to achieve is **transmutation**, or the conversion of an atom of one element into an atom of another element. This change can occur in at least two ways. **Transmutation can occur by radioactive decay or when particles bombard the nucleus of an atom.** The particles may be protons, neutrons, alpha particles, or small atoms.

Transmutations are common in nature. The production of carbon-14 from nitrogen-14 that takes place in the upper atmosphere is one example. Recall the decay series of uranium-238, which was described in Figure 25.8. In this series, 14 transmutations occur before a stable isotope of lead is produced. Some transmutations that do not occur in nature can be forced to occur in a laboratory or in a nuclear reactor. Ernest Rutherford performed the earliest artificial transmutation in 1919. He bombarded nitrogen gas with alpha particles. The results of this action are shown in Figure 25.9. As the nitrogen atoms absorb the alpha particles, they form fluorine-18 atoms.

$$^{14}_{7}\text{N} + ^{4}_{2}\text{He} \longrightarrow ^{18}_{9}\text{F}$$

Nitrogen-14 + Alpha particle → Fluorine-18

The unstable fluorine atoms quickly decay to form a stable isotope of oxygen and a proton.

$$^{18}_{9}\text{F} \longrightarrow ^{17}_{8}\text{O} + ^{1}_{1}\text{p}$$

Fluorine-18 → Oxygen-17 + Proton

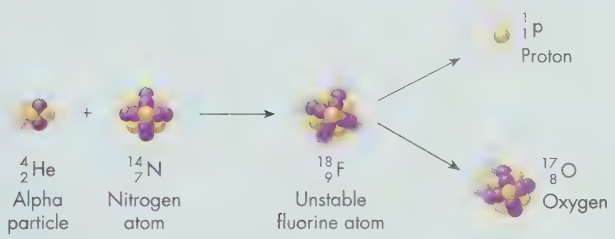

Figure 25.9 The Transmutation of Nitrogen-14
The first artificial transmutation reaction involved bombarding nitrogen gas with alpha particles.
Interpret Diagrams *Which particle is the intermediate in this nuclear reaction?*

Rutherford's experiment eventually led to the discovery of the proton. He and other scientists noticed a pattern as they did different transmutation experiements. In every case, hydrogen nuclei were emitted. Scientists realized that these hydrogen nuclei (protons) must have a fundamental role in atomic structure. James Chadwick's discovery of the neutron in 1932 also involved a transmutation experiment. Neutrons were produced when beryllium-9 was bombarded with alpha particles.

$$^{9}_{4}\text{Be} + ^{4}_{2}\text{He} \longrightarrow ^{12}_{6}\text{C} + ^{1}_{0}\text{n}$$

Beryllium-9 + Alpha particle → Carbon-12 + Neutron

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of four to complete the small-scale lab. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Restate the procedures and analysis questions in simpler terms. Complete the You're the Chemist questions as a class and have students copy the answers into their notebooks.

INTERMEDIATE: LOW/HIGH Discuss the Analyze and You're the Chemist questions with each lab group before students attempt them. Provide simple examples to remind students of mathematical concepts involved with graphing.

ADVANCED: LOW/HIGH Have students help beginning and intermediate speakers complete their analysis questions.

Explain

Transmutation Reactions

MAKING CONNECTIONS Explain that one of the main goals of medieval alchemists was the transmutation of common metals to precious metals. No chemical reaction can achieve this goal. However, through transmutations, modern chemists can change one element into another. Point out that transmutation reactions also allow chemists to produce elements that do not occur naturally.

Explore

Class Activity

PURPOSE Students will learn about and model an accelerator.

MATERIALS reference materials and Internet access, materials for making models

PROCEDURE Particle accelerators, such as linear accelerators, cyclotrons, and synchrotrons, are used in transmutation experiments. Divide the class into groups of four to five. Have each group choose one type of accelerator and conduct library research on its design and function. The group should create a model of the accelerator, which students can display and explain.

EXPECTED OUTCOME Models and explanations should show understanding of how transmutation is accomplished.

Answers

Sample Problem 25.1

9. 0.063 mg Mn-56

10. No, $(1/2)^2$, or 1/4, of the sample will remain.

FIGURE 25.9 the fluorine-18 atom

Evaluate

Informal Assessment

Have students describe how the ratio of neutrons to protons changes in nuclei that undergo beta particle and alpha particle emission. Then, have students explain the concept of half-life using a numerical example. *(Sample answer: initial state = 256 atoms; one half-life = 128 atoms; two half-lives = 64 atoms, and so on.)* Write several balanced and unbalanced nuclear equations on the board and have students identify and correct the unbalanced equations. Then have students complete the 25.2 Lesson Check.

Reteach

Point out the three natural processes that can result in a nucleus attaining a stable ratio of neutrons to protons:

- A beta emission increases the number of protons and decreases the number of neutrons.
- A positron emission decreases the number of protons and increases the number of neutrons.
- In heavy elements, the nucleus may emit an alpha particle, which decreases the numbers of both neutrons and protons.

Have students organize their notes by these three processes, and encourage them to add equations and examples to help facilitate their understanding.

Figure 25.10 Particle Accelerator
The Large Hadron Collider is the most powerful accelerator in the world. It has a circumference of about 27 kilometers and is about 100 meters underground. The accelerator is designed to mimic the conditions that existed right after the Big Bang.

Elements with atomic numbers above 92, the atomic number of uranium, are called **transuranium elements.** None of these elements occurs in nature, and all of them are radioactive. All transuranium elements undergo transmutation. These elements are synthesized in nuclear reactors and nuclear accelerators. Reactors produce beams of low-energy particles. Accelerators are used to increase the speed of bombarding particles to very high speeds. Sometimes particles must pass through a series of accelerators before they reach the desired speed. The European Oranization for Nuclear Research, known as CERN, has a number of accelerators at its site on the border between France and Switzerland. Figure 25.10 shows CERN's largest accelerator.

When uranium-238 is bombarded with the relatively slow neutrons from a nuclear reactor, some uranium nuclei capture these neutrons. The product is uranium-239.

$$^{238}_{92}\text{U} + {}^{1}_{0}\text{n} \longrightarrow {}^{239}_{92}\text{U}$$

Uranium-239 is radioactive and emits a beta particle. The other product is an isotope of the artificial radioactive element neptunium (atomic number 93).

$$^{239}_{92}\text{U} \longrightarrow {}^{239}_{93}\text{Np} + {}^{0}_{-1}\text{e}$$

Neptunium is unstable and decays, emitting a beta particle and a second artificial element, plutonium (atomic number 94).

$$^{239}_{93}\text{Np} \longrightarrow {}^{239}_{94}\text{Pu} + {}^{0}_{-1}\text{e}$$

Plutonium and neptunium are both transuranium elements. The majority of these elements do not occur in nature. Scientists in Berkeley, California, synthesized the first two artificial elements in 1940. Since that time, more than 20 additional transuranium elements have been produced artificially.

25.2 LessonCheck

11. Identify What factor determines the type of decay that occurs in a radioisotope?

12. Predict How much of a sample of radioisotope remains after one half-life? After two half-lives?

13. Explain How can transmutation occur in a stable isotope?

14. Apply Concepts Complete the following nuclear equations. Use what you know about balanced nuclear equations to identify the missing particles.

a. $^{27}_{13}\text{Al} + {}^{4}_{2}\text{He} \longrightarrow {}^{30}_{14}\text{Si} + ?$

b. $^{214}_{83}\text{Bi} \longrightarrow {}^{4}_{2}\text{He} + ?$

c. $^{27}_{14}\text{Si} \longrightarrow {}^{0}_{-1}\text{e} + ?$

d. $^{66}_{29}\text{Cu} \longrightarrow {}^{66}_{30}\text{Zn} + ?$

15. Calculate A radioisotope has a half-life of 4 days. How much of a 20-gram sample of this radioisotope remains at the end of each time period?

a. 4 days

b. 8 days

16. Calculate The mass of cobalt-60 in a sample decreased from 0.800 g to 0.200 g over a period of 10.5 years. From this information, calculate the half-life of cobalt-60.

17. Interpret Graphs Suppose the variable on the *x*-axis in Figure 25.7 were time instead of number of half-lives. Could the same graph be used to represent all radioisotopes? Why or why not?

Lesson Check Answers

11. the neutron-to-proton ratio

12. 50% of the sample remains after one half-life; 25% remains after two half-lives.

13. Transmutation can occur in a stable isotope when particles bombard its nuclei.

14. a. $^{27}_{13}\text{Al} + {}^{4}_{2}\text{He} \longrightarrow {}^{30}_{14}\text{Si} + {}^{1}_{1}\text{H}$

b. $^{214}_{83}\text{Bi} \longrightarrow {}^{4}_{2}\text{He} + {}^{210}_{81}\text{Tl}$

c. $^{27}_{14}\text{Si} \longrightarrow {}^{0}_{-1}\text{e} + {}^{27}_{15}\text{P}$

d. $^{66}_{29}\text{Cu} \longrightarrow {}^{66}_{30}\text{Zn} + {}^{0}_{-1}\text{e}$

15. a. 10 g

b. 5 g

16. 5.25 years

17. No, because radioisotopes have different half-lives.

Small-Scale Lab

Radioactivity and Half-Lives

Purpose

To simulate the transformation of a radioactive isotope over time, graph the data, and relate the data to radioactive decay and halflives.

Materials

- coin
- graph paper

Procedure

1. On a sheet of paper, make a data table similar to the one below.

2. For trial 1, flip a coin 100 times. In your table, record the total number of heads that result.

3. For trial 2, flip the coin the same number of times as the number of heads in trial 1. Record the number of flips and the number of heads that result.

4. Continue the procedure until you obtain no more heads.

Trial	Number of flips	Number of heads
1	100	
2		
3		
4		
5		
6		
7		
8		

Analyze

1. Graph Use graph paper to plot the number of flips (y-axis) versus the trial number (x-axis). Draw a smooth line to connect the points.

2. Interpret Graphs Is the rate of the number of heads produced over time linear or nonlinear? Is the rate constant over time or does it change?

3. Relate Cause and Effect Why does each trial reduce the number of heads by about one-half?

4. Use Models A half-life is the time required for one-half of the atoms of a radioisotope to decay to products. What value represents one half-life for the process of flipping coins?

You're the Chemist

1. Design an Experiment Design and carry out an experiment using a single die to model radioactive decay. Plot your data.

2. Calculate Radon-222 undergoes alpha decay, emitting an alpha particle (helium nucleus),

$$^{222}_{86}\text{Rn} \longrightarrow {}^{218}_{84}\text{Po} + {}^{4}_{2}\text{He}$$

Find the half-life of radon-222 in Table 25.2 and determine how long it takes for only one eighth of a sample of radon-222 to remain.

3. Calculate Carbon-14 undergoes beta decay, emitting a beta particle (electron),

$$^{14}_{6}\text{C} \longrightarrow {}^{14}_{7}\text{N} + {}^{0}_{-1}\text{e}$$

Find the half-life of carbon-14 in Table 25.2 and determine what fraction of the carbon-14 in a sample will remain after 11,460 years.

Small-Scale Lab

OBJECTIVE After completing this activity, students will be able to simulate the transformation of a radioactive isotope and relate simulated data to radioactive decay and half-life.

PREP TIME 5 minutes

CLASS TIME 20 minutes

TEACHING TIPS Emphasize that the trials involve flipping a coin to simulate radioactivity. The appearance and removal of a "head" represents the decay of an unstable nucleus. The rate of removal is analogous to the half-life of a radioactive isotope—around 50%. Although the number of heads decreases over time, the percent of heads produced remains relatively steady until the sample becomes too small. Point out that in a sample as small as 100, the likelihood of producing a number of heads other than 50 is high. If the sample size were increased, the relative error would decrease. As the sample size approaches zero, the results are no longer statistically reliable. Remind students that the probabilities relate to the overall sample, not to any individual coin or atom. Predictions for a mole of atoms, which provides a large sample, can be quite accurate.

EXPECTED OUTCOME For each trial, the number of heads is approximately half the number of flips.

ANALYZE

1. Student graphs should resemble the graph in Figure 25.7.
2. Nonlinear; the rate decreases over time.
3. For each flip, the probability of a head is 0.50.
4. one trial

YOU'RE THE CHEMIST

1. Count the total number of even numbers that occur in 100 rolls of the die. Roll the die again a number of times equal to the number obtained on the first trial. Do trials until the number of events equals zero. Plot number of evens versus trials.
2. After 3.8 days, half the sample remains. After 7.6 days, one-fourth remains. After 11.4 days, one-eighth remains.
3. This time period is two half-lives (11,460 years/5730 years = 2) of carbon-14. After two half-lives, one-fourth of the sample remains.

FOR ENRICHMENT Repeat the procedure four more times, using a new table for each trial. Average the results in each cell of the table for the five trials. **Ask** Which is closer to the expected values, the results from a single trial or the averaged results? *(The average values should be closer.)* As a class, discuss the advantages of using multiple trials in an experiment.

LESSON 25.3

Key Objectives

25.3.1 DESCRIBE what happens in a nuclear chain reaction.

25.3.2 DISTINGUISH fission reactions from fusion reactions.

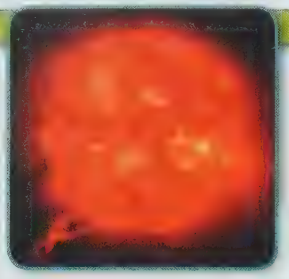
Engage

CHEMISTRY & YOU Explain that about 92% of all the sun's atoms are hydrogen. The second most abundant element is helium. **Ask** What can you infer about the reactant and product of the nuclear reaction that takes place in the sun? *(Hydrogen is the reactant and helium is the product.)*

Build Background



Have students brainstorm examples of chain reactions, such as a multi-car accident on an icy highway. Have students consider how these chain reactions often result in a significant number of collisions from the single initial collision, and the energy inputs and transfers required for the collisions to proceed.

IN ACADEMIC STANDARDS for SCIENCE

C.2.7 Compare and contrast nuclear reactions with chemical reactions. For nuclear reactions, describe how the fusion and fission processes transform elements present before the reaction into elements present after the reaction.

25.3 Fission and Fusion

C.2.7 Compare and contrast nuclear reactions with chemical reactions

CHEMISTRY & YOU

Q: *Where does the sun's energy come from?* The sun appears as a bright, fiery ball in the sky. The sun is so bright that you should never look at it directly without eye protection. The sun is about halfway through its life cycle. It has been producing energy for about 5 billion years and is expected to continue to produce energy for about 5 billion more. In this lesson, you will study the nuclear reaction that takes place in the sun.

Key Questions

What happens in a nuclear chain reaction?

How do fission reactions and fusion reactions differ?

Vocabulary

- fission
- neutron moderation
- neutron absorption
- fusion

Nuclear Fission

What happens in a nuclear chain reaction?

When the nuclei of certain isotopes are bombarded with neutrons, the nuclei split into smaller fragments. This process is called **fission.** Uranium-235 and plutonium-239, for example, are fissionable isotopes. Figure 25.11 shows how uranium-235 breaks into two smaller fragments of roughly the same size when struck by a slow-moving neutron. At the same time, more neutrons are released by the fission. These neutrons strike the nuclei of other uranium-235 atoms, which causes a chain reaction. **In a chain reaction, some of the emitted neutrons react with other fissionable atoms, which emit neutrons that react with still more fissionable atoms.**

Nuclear fission can release enormous amounts of energy. The fission of 1 kg of uranium-235, for example, yields an amount of energy equal to that produced when 20,000 tons of dynamite explode. In an uncontrolled nuclear chain reaction, all the energy is released in fractions of a second. An atomic bomb is a device that can trigger an uncontrolled nuclear chain reaction.

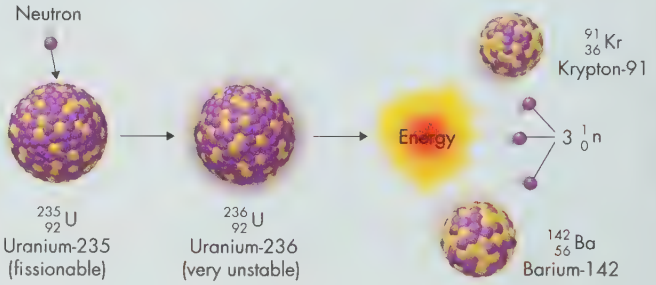


Figure 25.11 Fission of Uranium When struck by a slow-moving neutron, a uranium-235 nucleus breaks into two smaller nuclei and releases three neutrons. **Predict** ***What happens when the released neutrons strike other uranium-235 nuclei?***

Focus on ELL

1 CONTENT AND LANGUAGE Have students write the definitions of *fission* and *fusion* in their notebooks in their native language and in English. Have students prepare a two-column table to use to compare and contrast these two processes. Tell students to record sample reactions, and characteristics of each process as they progress through the lesson.

2 FRONTLOAD THE LESSON Have students preview Figures 25.11 and 25.14 and identify any similarities and differences that they find. Have students add these characteristics to their two-column table.

3 COMPREHENSIBLE INPUT Provide students with modeling clay. Have them work with a partner to model fission and fusion, using the diagrams in the lesson as a guide. Students should understand that fission is the breaking apart of a nucleus, and fusion is the combining of nuclei.

Fission can be controlled so energy is released more slowly. Nuclear reactors, such as the one shown in Figure 25.12, use controlled fission to produce useful energy. The reaction takes place within uranium-235 or plutonium-239 fuel rods. Much of the energy produced in this reaction is in the form of heat. A fluid, usually liquid sodium or water, removes heat from the core, or central part, of the reactor. Thus, the fluid is called a coolant. The heated fluid is used to change water to steam, which drives a turbine that generates electricity. The control of fission in a nuclear reactor involves two steps, neutron moderation and neutron absorption.

Neutron Moderation **Neutron moderation** is a process that slows down neutrons so the reactor fuel can capture them to continue the chain reaction. Moderation is necessary because most of the neutrons produced move so fast that they would pass right through a nucleus without being captured. Water and carbon in the form of graphite are good moderators.

Neutron Absorption To prevent the chain reaction from going too fast, some of the slowed neutrons must be trapped before they hit fissionable atoms. **Neutron absorption** is a process that decreases the number of slow-moving neutrons. Control rods, made of materials such as cadmium, are used to absorb neutrons. When the control rods extend almost all the way into the reactor core, they absorb many neutrons, and fission occurs slowly. As the rods are pulled out, they absorb fewer neutrons and the fission process speeds up. If the chain reaction were to go too fast, heat might be produced faster than the coolant could remove it. The reactor core would overheat, which could lead to mechanical failure and release of radioactive materials into the atmosphere. Ultimately, a meltdown of the reactor core might occur.

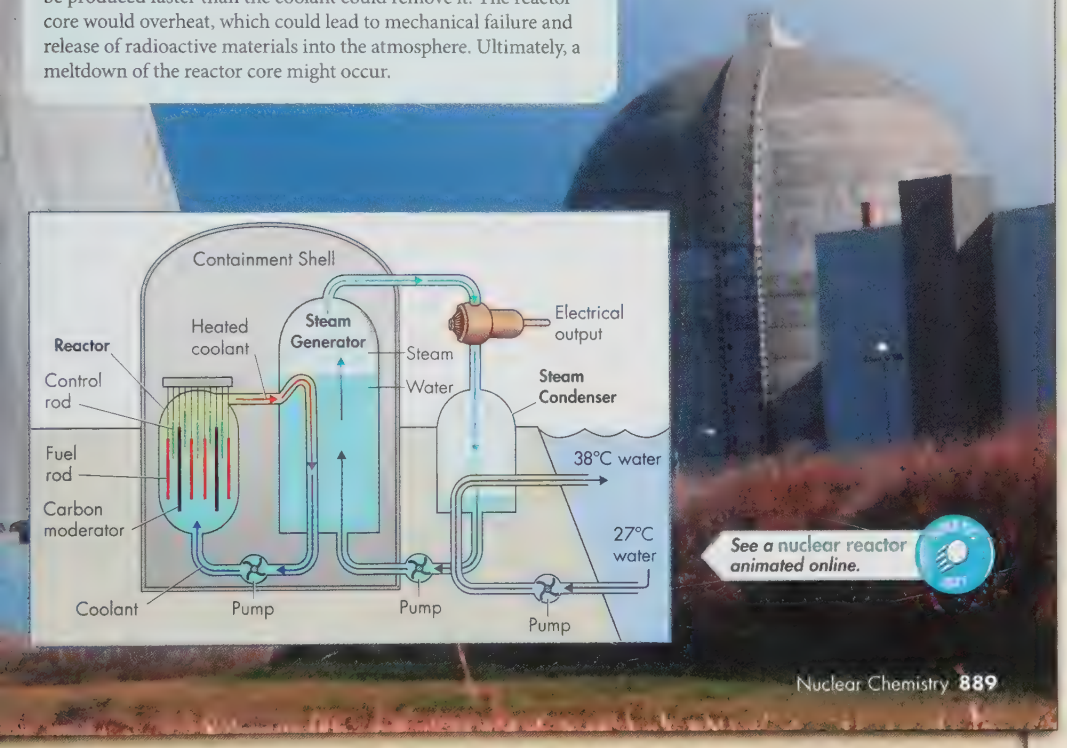

Figure 25.12 Nuclear Reactor
A nuclear reactor is used to produce electricity. A coolant absorbs heat produced by the controlled fission reaction and transfers the heat to water, which changes to steam. The steam drives a turbine, which drives a generator that produces electricity.
Interpret Diagrams *What happens to the steam after it drives the turbine?*

Differentiated Instruction

LPR LESS PROFICIENT READERS Explain that the term *fission* is generally used when an object splits into smaller parts. Demonstrate fission using rock candy crumbling into small pieces. Relate the concept of fission to fragmenting, breaking up, or crumbling. Explain that the term *fusion* is generally used when an object combine into a larger whole. Demonstrate fusion using popcorn pieces that are joined together to make a popcorn ball. Relate the concept of fusion to merging or joining together.

L3 ADVANCED STUDENTS Explain that the difference between the mass of a nucleus and the masses of the separated protons and neutrons is called the mass defect. Challenge students to use the mass defect and Albert Einstein's famous equation, $E = mc^2$, to calculate the energy released during a fission reaction.

L1 STRUGGLING STUDENTS After preparing the match demo, allow students to examine the matchstick chain. Project Figure 25.11 on the board, and identify parts of the chain that are equivalent to components of the U-235 reaction.

Foundations for Reading

BUILD VOCABULARY Explain that *fusion* is the noun form of the verb *fuse*, from the Latin word *fusus* meaning "melt together." Explain that during fusion, two nuclei combine to form a nucleus of larger mass.

READING STRATEGY Pair students and have them read each section silently. Have them record vocabulary that they find confusing. After the pair has finished a section, have them work together to help clarify any confusing concepts.

Explain

Nuclear Fission

USE VISUALS Display Figure 25.11 on an overhead projector and explain that uranium-235 is called a fissionable material because its nucleus becomes unstable when it is struck by a neutron. Note that three neutrons are produced by each fission event. Explain that fission reactions also produce radioactive waste products such as krypton-91 and barium-142.

USE MODELS Have students draw a diagram showing how the neutrons from a single fission process can induce subsequent fissions in other uranium-235 nuclei. The diagrams should illustrate the exponential nature of fission.

Explore

Teacher Demo

PURPOSE Students will observe a chain reaction.

MATERIALS wooden matchsticks

SAFETY Keep all flammable materials away from the demo area. Have a fire extinguisher ready.

PROCEDURE Cut some matchsticks in half and arrange the heads in branching chains on a non-combustible surface. The end of each matchstick should touch the heads of two other matchsticks, forming a "Y." Ignite the first matchstick head.

EXPECTED OUTCOME The matches ignite in a chain reaction.

Answers

FIGURE 25.11 They strike the nuclei of other fissionable atoms.

FIGURE 25.12 The steam is condensed into liquid water, which is pumped back into the steam generator.

Explain

Nuclear Fission

MAKE A CONNECTION Explain that the wastes produced in fission reactors contain isotopes with half-lives measured in the thousands or hundreds of thousands of years. Many proposals for storing or disposing of these wastes involve methods and materials that may be highly unsuitable. For example, the placement of wastes in thick drums that would then be sunk in the oceans—one suggested method—may contain the waste for only decades or a few centuries. The containers would begin to leak long before the contents were safe. The U.S. Department of Energy is responsible for cleaning up 130 nuclear sites and safely managing their waste. The sites include locations where uranium was milled, research labs, and former nuclear weapons production facilities. Have students research how the cleanups are progressing and how and where the nuclear waste is being disposed.

Extend

Have students work in groups of four. Tell them that each group has to create and implement a simulation that is analogous to a uranium fission chain reaction. Groups should be prepared to show their simulation during class. *(Sample simulations: the "wave" at a sporting event, house of cards, and so on.)*

Explain

Nuclear Fusion

Generate a discussion about the limitations of using fusion as an alternative energy source. Point out that the only known way of generating the necessary heat to start a fusion reaction is to use a fission bomb—an uncontrolled reaction. Currently, no known materials or engineering designs exist that could withstand either the temperatures or the necessary fission-generated explosion. As a result, scientists have been pursuing the possibility of finding a situation in which fusion would occur at room temperature, a process called *cold fusion*. Have students research the history and current state of cold fusion research, and write a report explaining their findings.

CHEMISTRY & YOU Explain that the sun contains hydrogen nuclei, and that a proton is in a hydrogen nucleus. **Ask** How is the energy of the sun produced? *(Energy is released during the formation of helium nuclei.)*

READING SUPPORT

Build Reading Skills:
Inference When you make an inference, you are really reading between the lines. An inference should be based on information in the text and any background knowledge you may have. After you read the Nuclear Waste section, use inference to explain how the storage of nuclear wastes could affect the environment.

Nuclear Waste Fuel rods from nuclear power plants are one major source of nuclear waste. The fuel rods are made from a fissionable isotope, either uranium-235 or plutonium-239. The rods are long and narrow—typically 3 meters long with a 0.5-cm diameter. In a typical reactor, three hundred fuel rods are bundled together to form an assembly, and one hundred assemblies are arranged to form the reactor core. During fission, the amount of fissionable isotope in each fuel rod decreases. Eventually the rods no longer have enough fuel to ensure that the output of the power station remains constant. The isotope-depleted, or spent, fuel rods must be removed and replaced with new fuel rods.

Spent fuel rods are classified as high-level nuclear waste. They contain a mixture of highly radioactive isotopes, including fission products and what remains of the nuclear fuel. Some of these fission products have very short half-lives, on the order of fractions of seconds. Others have half-lives of hundreds or thousands of years. All nuclear power plants have holding tanks, or "swimming pools," for spent fuel rods. Water cools the spent rods, and also acts as a radiation shield to reduce the radiation levels. The pools, like the one shown in Figure 25.13, are typically 12 meters deep. Storage racks at the bottom of these pools are designed to hold the spent fuel assemblies. The rods continue to produce heat for years after their removal from the core.

The spent fuel rods may spend a decade or more in a holding tank. In the past, plant operators expected spent fuel rods to be reprocessed. Any leftover fissionable isotope in the rods would be recycled in the manufacture of new fuel rods. However, with large deposits of uranium ore available—many in the United States—it is less expensive to mine new fuel than to reprocess depleted fuel. At some nuclear plants, the storage pool has no space left. In order to keep these plants open, their fuel rods must be moved to off-site storage facilities. Finding appropriate storage sites is difficult because high-level waste may need be stored for a long time. Plutonium-239, for example, will not decay to safe levels for 20,000 years. Often, people are concerned about having nuclear waste stored nearby or shipped through their communities.

Figure 25.13 Disposal of Fuel Rods Racks at the bottom of this pool contain spent fuel rods. The blue glow is from beta particles that the rods emit into the water.

Professional Development Note

Nuclear Waste

Nuclear waste began accumulating in the 1940s at nuclear weapon facilities, which no longer operate. Today, nuclear waste is created by power plants, and sectors of society, such as hospitals, that use radioisotopes. The nuclear waste accumulated over decades has been in temporary storage awaiting methods for permanent disposal. The waste is classified as low-, mid- or high-level. Transuranic waste is low- to -mid-level waste contaminated with alpha-emitting radioisotopes with half-lives greater than 20 years and atomic numbers greater than 92. This waste consists of disposable items such as tools or clothing. High-level nuclear waste consists of spent fuel rods from nuclear reactors and the waste from the production of nuclear weapons.

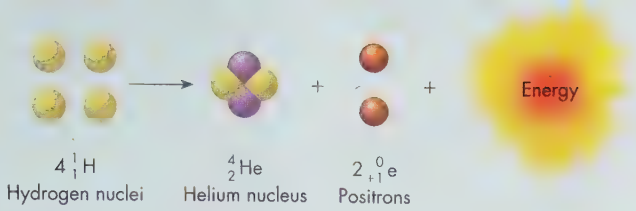

Figure 25.14 Fusion in the Sun
In the sun, hydrogen nuclei fuse to produce helium nuclei.
Interpret Diagrams *What are the other products of this reaction?*

Nuclear Fusion

How do fission reactions and fusion reactions differ?

The sun, directly and indirectly, is the source of most energy used on Earth. The energy emitted by the sun results from nuclear fusion. **Fusion** occurs when nuclei combine to produce a nucleus of greater mass. In solar fusion, hydrogen nuclei (protons) fuse to make helium nuclei. Figure 25.14 shows that the reaction also produces two positrons. **Fusion reactions, in which small nuclei combine, release much more energy than fission reactions, in which large nuclei split apart and form smaller nuclei.** However, fusion reactions occur only at very high temperatures—in excess of 40,000,000°C.

The use of controlled nuclear fusion as an energy source on Earth is appealing. The potential fuels are inexpensive and readily available. Some scientists are studying a reaction in which a deuterium (hydrogen-2) nucleus and a tritium (hydrogen-3) nucleus combine to form a helium nucleus.

$$ {}^{2}_{1}H + {}^{3}_{1}H \longrightarrow {}^{4}_{2}He + {}^{1}_{0}n + \text{energy} $$

The problems with fusion lie in achieving the high temperatures needed to start the reaction and in containing the reaction once it has started. The high temperatures required to start fusion reactions have been achieved by using a fission bomb. Such a bomb is the triggering device used for setting off a hydrogen bomb, which is an uncontrolled-fusion device. This process is of no use, however, as a controlled generator of power.

CHEMISTRY & YOU

Q: *The high temperatures needed to support fusion exist within the sun's core. Late in the sun's life cycle, other fusion reactions will occur. What element would form when two helium nuclei fuse?*

25.3 LessonCheck

18. Relate Cause and Effect Explain what happens in a nuclear chain reaction.

19. Compare How are fusion reactions different from fission reactions?

20. Explain What is neutron moderation, and why is it necessary in a nuclear reactor?

21. Identify What are two sources of the radioactive nuclei present in spent fuel rods?

22. Evaluate Suppose the technical problems with fusion reactors could be overcome. What are some advantages to using a fusion reactor to produce electricity?

23. Interpret Diagrams Review the diagram of a reactor in Figure 25.12. What role does water play in a typical nuclear reactor?

24. Infer Some nuclear waste is stored about 600 meters below the desert in New Mexico inside caverns dug out of an ancient bed of rock salt. The land above the storage site is owned by the federal government. Why do you think this location was chosen?

25. Describe Read about heavy water reactors on page R35 of the Elements Handbook. What is the advantage of using heavy water instead of ordinary water as a neutron moderator?

Lesson Check Answers

18. Fissionable atoms emit neutrons, which react with other fissionable atoms, which emit more neutrons.

19. In fission reactions, nuclei are split into smaller nuclei. In fusion reactions, small nuclei combine to form larger nuclei. Fusion reactions produce a greater amount of energy.

20. A neutron moderator slows down neutrons so that the nuclei in the reactor fuel can capture them.

21. unused nuclear fuel and fission products

22. The potential fuels are readily available and inexpensive.

23. Water absorbs heat from the reactor. The steam produced is used to generate electricity. Water is also used to condense the steam.

24. *Sample answer:* The site is below ground in an unpopulated area that is controlled by the government.

25. D_2O is a more efficient moderator than H_2O. So in heavy-water reactors, the fuel does not need to be enriched.

Evaluate

Informal Assessment

Ask students to write nuclear equations describing fission and fusion. **Ask** How might a meltdown of a nuclear reactor occur? *(Rapid removal of the control rods could allow too many neutrons to react with fissionable nuclei.)* **Ask** Describe the conditions under which nuclear fusion will occur. *(temperatures in excess of 4.00×10^{7}°C; methods to confine and control the reaction are needed)* Then have students complete the 25.3 Lesson Check.

Reteach

Explain that both nuclear fission and nuclear fusion produce energy by the conversion of matter to energy. In fission, heavy nuclei are split into lighter nuclei. In fusion, light nuclei combine to form heavier nuclei. Fission reactions are relatively easy to control but produce radioactive wastes. Fusion reactions are difficult to initiate and control but produce little radioactive waste. Guide students in creating a concept map to help them organize the content in this lesson.

Answers

READING SUPPORT *Sample answer:* Leakage from a storage site could contaminate groundwater and, subsequently, soil.

FIGURE 25.14 positrons

CHEMISTRY & YOU

ACTIVATE PRIOR KNOWLEDGE Make sure students understand the role power plants play in an industrial society. **Ask** What is the purpose of a power plant? *(to generate electricity)* **Ask** What parts of a community need a reliable supply of electricity? *(homes, businesses, medical facilities, factories, and so on)* Ask students who have experienced a power outage to describe the effects of the outage.

Explain

USE VISUALS Have students use the illustrations and the table to make a list of similarities and differences between traditional nuclear power plants and small-scale nuclear power plants. *(Similarities: controlled fission reaction, steam used to generate electricity, nuclear waste. Differences: size of facility, construction time, location of reactors, method for circulating coolant, ability to continue operating if there is a problem with a reactor.)*

START A CONVERSATION Explain that problems with disposal of nuclear wastes have led some people to propose that nuclear power be abandoned as a source of energy. After students read the feature, ask students whether they think that the proposed small-scale reactors will change some people's minds.

CHEMISTRY & YOU: TECHNOLOGY

Small-Scale Nuclear Power

About 20 percent of the electricity generated each year in the United States comes from nuclear power. Operating costs for nuclear power plants are lower than for plants that burn fossil fuels. However, a nuclear power plant, like the one shown in the photo, costs more and takes longer to build than a coal-burning plant. Also, people have concerns about the safety of these plants.

Plants that burn fossil fuels also have issues. Concerns about global warming have made the reduction of carbon emissions a priority for many countries. To meet this goal, plants that burn fossil fuels must install technology to trap the carbon dioxide produced when coal or natural gas burn. A greater reliance on nuclear power can help reduce carbon emissions.

Researchers at Oregon State University have proposed a new kind of nuclear power plant to address some of the problems presented by traditional plants. The large above-ground reactor of a traditional plant would be replaced by self-contained modules, which would be located sixty-five feet below ground level. The plant could open with only a few modules. More modules can be added as needed.

Old vs. New

	Traditional Plant	Small-Scale Plant
Construction	Single-unit plants must be built onsite. Construction time is 7–10 years.	Modular units are factory-built and shipped to the site. Construction time is 3–3.5 years.
Coolant method	Valves and pumps circulate the coolant around the reactor core.	Gravity, condensation, evaporation, and convection circulate the coolant.
Safety	The reactor is above ground. A backup electricity source is needed for coolant systems. If the reactor must be shut down, no electricity is generated.	The modules are underground, in self-contained steel chambers, immersed in a pool of water. One module can be shut down without affecting the other modules.
Facility size	Many traditional single-unit plants require about 20 acres.	A plant that provides as much electricity as a small traditional plant would require about 4 acres.

Professional Development Note

Nuclear Power

As of 2010, 436 nuclear power plants were in operation worldwide and about 30 countries got some of their electricity from nuclear power. In France, over 75% of electricity is generated from nuclear power. By contrast, only about 20% of the electricity generated in the United states comes from nuclear power. The Nuclear Regulatory Commission (NRC), which was established in 1974, is the agency that ensures the safe use of nuclear materials for civilian purposes. It is the NRC that must approve any new design for a nuclear power plant. A design certification is valid for 15 years, but can be renewed for an additional 10 to 15 years. Approval of a design application is independent from approval of the construction or operation of a nuclear power plant.

Take It Further

1. **Interpret Tables** Why doesn't the small-scale plant need a backup source of electricity for its coolant systems?
2. **Evaluate** Nuclear power plants often provide power for large cities. What aspects of the new plants would make them useful to rural areas?
3. **Identify** Which safety concern related to nuclear power is not addressed by the small-scale plants?

Extend

Connect to HISTORY

Tell students that the first large-scale nuclear power plant in the United States was built in Shippingport, Pennsylvania, a town about 35 miles northwest of Pittsburgh. The plant came on line December 18, 1957. One of the reasons that the plant was built in the middle of Pennsylvania coal country was that residents were not happy with the air pollution associated with coal-burning power plants. Engineers learned a lot from this first plant, including how to decommission a reactor when the plant was shut down in the 1980s.

ANALYZE DATA Display a copy of the map showing the locations of operating nuclear power reactors from the NRC web site. Have students compare the map with a population density map of the United States and identify the relationship between the data.

Answers

TAKE IT FURTHER

1. Pumps, which depend on electricity, are not used to circulate the coolant.
2. *Sample answer:* With a modular approach, a larger number of smaller plants could be constructed to serve a more scattered population.
3. The issue of nuclear waste is not addressed by the small-scale plants.

LESSON 25.4

Key Objectives

25.4.1 IDENTIFY three devices that are used to detect radiation.

25.4.2 DESCRIBE some practical uses of radioisotopes.

Additional Resources

Reading and Study Workbook, Lesson 25.4

Available Online or on Digital Media:

- Teaching Resources, Lesson 25.4
- Laboratory Manual, Lab 52

Engage

CHEMISTRY & YOU Have students study the photograph and read the text that opens the section. Am-241 undergoes α decay. **Ask** What is the other product of the decay of an Am-241 nucleus? *(Np-237)* **Ask** Why do you have to exert special care in disposing of these smoke detectors? *(The detectors still contain radioactive materials.)*

Build Background

Lead a class discussion about the pros and cons of radiation exposure. Allow time for students to share personal knowledge involving radiation. Have students find recent articles in medical journals about the benefits of using radiation in treatments, as well as articles about the harmful consequences of radiation exposure.

IN ACADEMIC STANDARDS for SCIENCE

- Develop explanations based on reproducible data and observations gathered during laboratory investigations.
- Clearly communicate their ideas and results of investigations verbally and in written form using tables, graphs, diagrams, and photographs.

C.2.7 Compare and contrast nuclear reactions with chemical reactions. For nuclear reactions, describe how the fusion and fission processes transform elements present before the reaction into elements present after the reaction.

25.4 Radiation in Your Life

C.2.7 Compare and contrast nuclear reactions with chemical reactions

CHEMISTRY & YOU

Q: *How does a smoke detector work?* Smoke detectors can limit injuries or deaths due to fires. A typical household smoke detector contains a small amount of americium, $^{241}_{95}Am$, in the form of AmO_2. Americium-241 is a radioisotope. When the air is smoke-free, a current flows through the smoke detector. When smoke is present, there is a drop in current. This drop is detected by an electronic circuit, which causes an alarm to sound. This lesson will help you understand the role of radiation in smoke detection.

Key Questions

- ***What are three devices used to detect radiation?***
- ***What are some practical uses of radioisotopes?***

Vocabulary

- ionizing radiation

CHEMISTRY & YOU

Q: *Radiation emitted in a smoke detector ionizes the nitrogen and oxygen in air, and a current flows. When smoke particles attach to the ions, the ions lose their charge. What happens next?*

Detecting Radiation

What are three devices used to detect radiation?

Radiation emitted by radioisotopes has enough energy to knock electrons off some atoms of a bombarded substance, producing ions. Thus, the radiation emitted by radioisotopes is called **ionizing radiation.** It is not possible for humans to see, hear, smell, or feel ionizing radiation. So people must rely on detection devices to alert them to the presence of radiation and to monitor its level. These devices work because of the effects of the radiation when it strikes atoms or molecules in the detector. For example, the radiation can expose a photographic plate, which produces an image such as the one shown in Figure 25.15. When the plate is developed, its darkened areas show where the plate has been exposed to radiation. Some devices rely on the current produced when atoms are ionized. **Geiger counters, scintillation counters, and film badges are commonly used to detect radiation.**

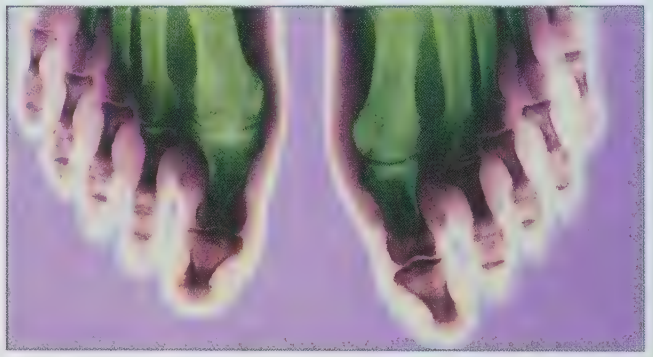

Figure 25.15 X-Rays X-rays allow doctors to see inside the body without having to cut into the body. Color was added to highlight parts of the image.

Focus on ELL

1 CONTENT AND LANGUAGE Discuss the term *ionizing radiation*. Explain that there are many types of radiation, such as visible light, microwaves, and gamma radiation. Explain that only high-energy radiation has enough energy to knock electrons off atoms.

2 FRONTLOAD THE LESSON Some students or their family members may have undergone medical tests or treatments that involved swallowing a radioactive substance. Some students may have relatives that work with radioactive materials. If they are willing, have students share their experiences. List the experiences on the board and refer back to them as you proceed with the lesson.

3 COMPREHENSIBLE INPUT Take students on a picture walk through the lesson. Have them look at each picture or diagram and read the caption. Afterwards, have them summarize what they will learn about in the lesson. If possible, provide, a smoke detector, a Geiger counter and a film badge for students to examine.

Geiger Counter A Geiger counter uses a gas-filled metal tube to detect radiation. The tube has a central wire electrode that is connected to a power supply. When ionizing radiation penetrates a thin window at one end of the tube, the gas inside the tube becomes ionized. Because of the ions and free electrons produced, the gas is able to conduct electricity. Each time a Geiger tube is exposed to radiation, current flows. The bursts of current drive electronic counters or cause audible clicks from a built-in speaker. Geiger counters can detect alpha, beta, and gamma radiation. The first small, hand-held Geiger counters were developed in the 1930s.

Astronomers use Geiger counters to detect cosmic rays from outer space. Geologists use Geiger counters to search for radioactive minerals, such as uranium ores. These devices are also used to check for leaks in hospitals and other places that use radiation. Figure 25.16 shows one use for a Geiger counter.

Scintillation Counter A scintillation counter uses a phosphor-coated surface to detect radiation. When ionizing radiation strikes the surface, the phosphor produces bright flashes of light, or scintillations. The number of flashes and energies are detected electronically. The data is then converted into electronic pulses, which are measured and recorded. Scintillation counters are more sensitive than Geiger counters. This means that they can detect some radiation that would not be detected by a Geiger counter. Scintillation counters are used to track the path of radioisotopes through the body. They are also used to monitor the possible transport of radioactive materials across national borders and through airports.

Film Badge Figure 25.17 is a diagram of a typical film badge. The badge contains layers of photographic film covered with black light-proof paper. The film is sealed in a plastic or metal holder. To reach the film, radiation must pass through a filter, which absorbs some radiation, or a transparent area through which radiation can pass easily. People who work with or near ionizing radiation must wear a film badge to monitor their exposure while they are at work. At specific intervals, the film is removed and developed. The strength and type of radiation exposure are determined by comparing the darkness of the film in all the exposed areas. Records are kept of the results. Film badges do not protect a person from radiation, but they do monitor the degree of exposure. To protect themselves, workers must keep a safe distance from the source and use adequate shielding.

Figure 25.16 Geiger Counters
This person is using a Geiger counter to check for pockets of radiation in contaminated dirt at a spill site.

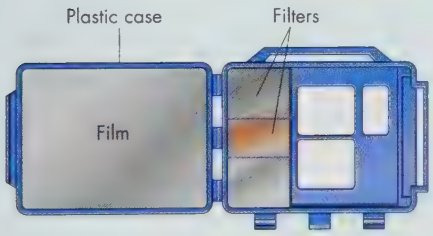

Figure 25.17 Film Badge
In a film badge, radiation passes through one of several filters or through a transparent area before it strikes the film. Different amounts of radiation pass through each area.

Foundations for Reading

BUILD VOCABULARY Point out that the suffix *-ize* means "to make." Thus, *ionizing* radiation is able to make ions.

READING STRATEGY Encourage students to take a leadership role in reading this section. Have students take turns reading and conducting discussions about what was read.

Explain

Detecting Radiation

APPLY CONCEPTS Explain that a Geiger counter is mainly used to detect beta radiation because alpha particles cannot penetrate the tube and gamma rays pass through without causing many ionizations. By contrast, scintillation counters are designed to detect all types of radiation. However, they are not generally portable. The film badge is a updated version of Becquerel's photographic plate.

USE AN ANALOGY Given the changes in how computer and television screens display images, the only object that students may have seen that relies on a phosphor coating is a fluorescent light.

CHEMISTRY & YOU When ions in a smoke detector lose their charge, the current drops, which triggers an alarm.

Explore

Teacher Demo

PURPOSE Students will observe background radiation.

MATERIALS Geiger counter

PROCEDURE Using a Geiger counter equipped with a rate meter and a loudspeaker, have students listen to the random clicking noise. Be sure that there are no radioactive sources nearby. Point out that the counter is recording background radiation, which is always present. **Ask** What are possible sources of background radiation? *(cosmic, soil, and interior of Earth)* Explain that background radiation varies from location to location. To make an accurate measurement of radiation from a given source, local background radiation must be taken into account. Next, place the Geiger counter near an object containing a radioisotope, such as a smoke detector.

EXPECTED OUTCOME The Geiger counter indicates small amounts of background radiation and larger amounts near a source of radioactivity.

Professional Development Note

Gold-Foil Experiment

Hans Geiger (1882–1945) was a student of Ernest Rutherford. It was Geiger, along with another student named Marsden, who carried out the gold-foil, alpha-scattering experiment at Rutherford's direction. Geiger gained experience with the problem of detecting radiation, which ultimately led to his invention of the Geiger counter. Ask students to review the gold-foil experiment and describe the detection method used to measure the scattering of alpha particles. This method was a precursor of the scintillation counter.

Explore

QuickLab

OBJECTIVE After completing this activity, students will be able to demonstrate the relationship between radiation intensity and the distance from the radiation source.

SKILLS FOCUS observing, measuring, using graphs, calculating

PREP TIME 20 minutes

CLASS TIME 30 minutes

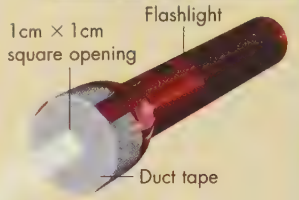
EXPECTED OUTCOME As distance increases, intensity decreases and area increases.

ANALYZE AND CONCLUDE

1. Intensity is inversely related to the square of the distance.
2. When the distance is doubled, area increases by a factor of four, and intensity is one-fourth as much. When the distance is tripled, the area increases by a factor of nine, and the intensity is one-ninth as much.

ENRICHMENT Have students repeat the Quick Lab two times, changing the size of the hole from what it is in the original lab. On one trial, the hole should be slightly larger. On the other trial, the hole should be slightly smaller. **Ask** Does the size of the hole affect the results? *(No, the results are the same.)*

QuickLab



Inverse-Square Relationships

Purpose To demonstrate the relationship between radiation intensity and the distance from the radiation source

Materials

- flashlight
- strips of duct tape
- scissors
- poster board, white (50 cm × 50 cm)
- meter ruler or tape measure
- flat surface, long enough to hold the meter ruler
- graph paper

Procedure

1. Estimate and record the distance (A) from the bulb filament to the front surface of the flashlight.
2. Cover the end of a flashlight with strips of duct tape. Leave a 1 cm × 1 cm square slit in the center of the tape.
3. Place the flashlight on its side on a flat surface. Turn on the flashlight. Darken the room.
4. Mount a large piece of white poster board in front of the flashlight, perpendicular to the horizontal surface.
5. Move the flashlight away from the board in short increments. At each position, record the distance (B) from the flashlight to the board and the length (L) of one side of the square image on the board.
6. On a sheet of graph paper, plot L on the y-axis versus $A + B$ on the x-axis. On another sheet, plot L^2 on the y-axis versus $A + B$ on the x-axis.

Analyze and Conclude

1. **Make Generalizations** As the flashlight is moved away from the board, what happens to the intensity of the light in the square image? Use your graphs to describe the relationship between intensity and distance.
2. **Explain** When the distance of the flashlight from the board (B) is doubled and tripled, what happens to the areas and intensities of the squares?

Using Radiation

What are some practical uses of radioisotopes?

Although radiation can be harmful, it can be used safely and has many important applications. **Radioisotopes are used to analyze matter, study plant growth, diagnose medical problems, and treat diseases.**

Analyzing Matter Scientists use radiation to detect trace amounts of elements in samples. The process is called neutron activation analysis. A sample is bombarded with neutrons from a radioactive source. Some atoms in the sample become radioactive. The half-life and type of radiation emitted can be detected and analyzed by a computer. Because this data is unique for each isotope, scientists can determine what radioisotopes were produced and infer what elements were in the original sample. Museums use this process to detect art forgeries. Crime laboratories use it to analyze gunpowder residues.

Using Tracers Radioisotopes called tracers are used in agriculture to test the effects of herbicides, pesticides, and fertilizers on plants. A tracer is introduced into the substance being tested. Next, plants are treated with the tagged substance. Devices that detect radioactivity are used to locate the substance in the plants. The tracer may also be monitored in animals that consume the plants, as well as in water and soil.

Focus on ELL

4 LANGUAGE PRODUCTION Have students work in groups of two to complete the lab. Make sure each group has ELLs of varied language proficiencies, so that more proficient students can help less proficient ones. Have students work according to their proficiency level.

BEGINNING: LOW/HIGH Restate each step of the Procedure in simpler words. Answer the Analyze and Conclude questions as a class.

INTERMEDIATE: LOW/HIGH Discuss the lab steps before students begin. Be sure they understand difficult words such as *filament, slit,* and *perpendicular.* Have students work with a partner to answer the Analyze and Conclude questions.

ADVANCED: LOW/HIGH Have students pre-read the lab and ask any questions before they begin. Have students help less proficient students plot the graph.

Diagnosing Medical Problems Radioisotopes can be used to detect disorders of the thyroid gland, which is located in the throat. The main function of this gland is to control the rate at which your cells release energy from food. The thyroid gland extracts iodide ions from blood and uses them to make the hormone thyroxine. To diagnose thyroid disease, the patient is given a drink containing a small amount of the radioisotope iodine-131. After about two hours, the amount of iodide uptake is measured by scanning the patient's throat with a radiation detector. Figure 25.18 shows the results of such a scan. In a similar way, the radioisotope technetium-99m is used to detect brain tumors and liver disorders. Phosphorus-32 is used to detect skin cancer.

Treating Diseases Radiation is one method used in the treatment of some cancers. Cancer is a disease in which abnormal cells in the body are produced at a rate far beyond the rate for normal cells. The mass of cancer cells that result from this runaway growth is called a tumor. Fast-growing cancer cells are more susceptible to damage by high-energy radiation such as gamma rays than are healthy cells. Thus, radiation can be used to kill the cancer cells in a tumor. Some normal cells are also killed, however, and cancer cells at the center of the tumor may be resistant to the radiation. Therefore, the benefits of the treatment and the risks to the patient must be carefully evaluated before radiation treatment begins. Cobalt-60 and cesium-137 are typical radiation sources for cancer therapy.

Salts of radioisotopes can also be sealed in gold tubes and directly inserted in tumors. This method of treatment is called seeding. The salts emit beta and gamma rays that kill the surrounding cancer cells. Because the radioisotope is in a sealed container, it is prevented from traveling to other parts of the body.

Prescribed drugs containing radioisotopes of gold, iodine, or phosphorus are sometimes used in radiation therapy. For example, a dose of iodine-131 larger than that used to detect thyroid diseases can be given to a patient to treat the disease. The radioactive iodine passes through the digestive system into the blood, which carries it to the thyroid. The iodine that collects in the gland emits beta particles and gamma rays , which provide therapy.

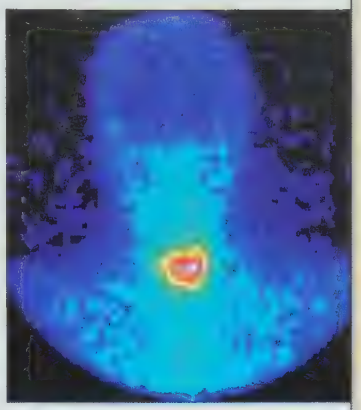


Figure 25.18 Radioactive Tracer This scanned image of a thyroid gland shows where radioactive iodine-131 has been absorbed. Doctors use these images to identify thyroid disorders.

25.4 LessonCheck

26. Compare In each of the three detection devices described in the lesson, what is used to detect the radiation?

27. Review What are two ways radioisotopes can be used in medicine?

28. Define Why is the radiation emitted by radioisotopes called ionizing radiation?

29. Explain Suppose you worked with or near a radiation source. Why might your employer use a film badge rather than a Geiger counter to monitor your exposure to radiation?

30. Infer Why do airports use scintillation counters and not Geiger counters to search for radioactive materials?

31. Compare Of Geiger counters, scintillation counters, and film badges, which device is most similar to a smoke detector? Explain your choice.

32. Sequence Briefly describe the three steps that occur when iodine-131 is used to diagnose thyroid disease?

33. Explain What is one advantage of using sealed tubes, or seeds, to treat a tumor?

Lesson Check Answers

26. Geiger counter: an inert gas; scintillation counter: phosphor-coated surface; film badge: photographic film

27. for diagnosis and treatment of diseases

28. It can knock electrons off atoms, causing them to become charged.

29. A Geiger counter measures the radiation emitted by a source at a given time. A film badge monitors exposure to radiation over time.

30. Scintillation counters can detect radiation that would not be detected by a Geiger counter.

31. A Geiger counter, because it also depends on a flow of electric current

32. Patient drinks mixture containing I-131; thyroid gland absorbs iodine; amount of uptake is measured.

33. The effect of the radioisotope is limited to a small area.

Extend

Connect to MEDICINE

The branch of medicine that deals with radioactive isotopes is called nuclear medicine. Tell students that many of the radioactive isotopes used in medicine are not naturally occurring; they are produced artificially by methods such as neutron bombardment. Explain that radioisotopes are used by physicians to diagnose and treat some forms of cancer. Point out that actively dividing cells are usually more sensitive to radiation than are normal cells. **Ask** What characteristic is important to consider when choosing a radioisotope as a treatment for cancer? *(The half-life should be long enough to kill the cancer cells but short enough to limit a patient's exposure.)* Explain that radioisotopes used in nuclear medicine typically have half-lives of a few days or less. Have interested students research the consequences of over-exposure to alpha, gamma, and beta radiation and present their findings in a poster.

Evaluate

Informal Assessment

Provide students with a two-column chart. Have students use the chart to compare and contrast detection of radiation by a film badge and detection of radiation by a scintillation counter. On the back of the chart, have students list or describe two practical uses of radioactive isotopes. *(Sample answer: as tracers to study plant growth and in the treatment of cancer)* Then have students complete the 25.4 Lesson Check.

Reteach

Review with students the three types of radiation detectors. Explain that, those devices do not protect the user from exposure to radiation. Note that workers who work with or near radioisotopes often wear special clothing, such as lead aprons or specialized self-contained suits, to shield themselves from certain types of radiation.

STUDY GUIDE

Evaluate

Review and Assessment Materials

WALK-THRU TUTORIALS Each of the Math Tune-Up problems on the following page has an animated step-by-step tutorial that explains the problem-solving strategy in detail.

PROBLEM SETS Have students practice more chemical quantity problems by using the Chapter 25 Online Problem Set.

MATH SKILLS REVIEW Have struggling students practice solving algebraic equations by using the MathXL learning module.

VIRTUAL LABS Have students complete a virtual lab as an in-class or take-home assignment to help reinforce the mathematical relationships associated with radioactive decay.

Study Tip

Show all your calculations when working problems. Writing down the steps of a calculation helps you think through each step in the thought process of problem solving. Also, if you don't show your calculations, you will have more difficulty finding the source of your error if you made a mistake.

25 Study Guide

BIG IDEA ELECTRONS AND THE STRUCTURE OF ATOMS

Unstable atomic nuclei decay by emitting alpha or beta particles. Often gamma rays are emitted, too. During fission and fusion, atoms change their chemical identity as the number of protons in their nuclei change. In fission, large nuclei split into two or more smaller nuclei. In fusion, smaller nuclei combine to form larger nuclei at extremely high temperature and pressure. The ability to detect particles emitted when nuclei decay helps scientists study processes that take place in living organisms, This ability also allows scientists to determine the age of fossils and other objects.

25.1 Nuclear Radiation

- Unlike chemical reactions, nuclear reactions are not affected by changes in temperature, pressure, or the presence of catalysts. Also, nuclear reactions of a given radioisotope cannot be slowed down, speeded up, or stopped.
- Three types of nuclear radiation are alpha radiation, beta radiation, and gamma radiation.

- radioactivity (876)
- nuclear radiation (876)
- radioisotope (876)
- alpha particle (877)
- beta particle (878)
- gamma ray (879)

25.2 Nuclear Transformations

- The neutron-to-proton ratio in a radioisotope determines the type of decay that occurs.
- After each half-life, half of the original radioactive atoms have decayed into atoms of a new element.
- Transmutation can occur by radioactive decay, or when particles bombard the nucleus of an atom.

- nuclear force (880)
- band of stability (880)
- positron (881)
- half-life (882)
- transmutation (885)
- transuranium elements (886)

Key Equation

$$A = A_0 \times \left(\frac{1}{2}\right)^n$$

25.3 Fission and Fusion

- In a chain reaction, some of the emitted neutrons react with other fissionable atoms, which emit neutrons that react with still more fissionable atoms.
- Fusion reactions, in which small nuclei combine, release much more energy than fission reactions, in which large nuclei split apart to form smaller nuclei.

- fission (888)
- neutron moderation (889)
- neutron absorption (889)
- fusion (891)

25.4 Radiation in Your Life

- Geiger counters, scintillation counters, and film badges are commonly used to detect radiation.
- Radioisotopes are used to analyze the composition of matter, study plant growth, diagnose medical problems, and treat diseases.

- ionizing radiation (894)

UbD

Understanding by Design

Performance Tasks

DECAYING GRACEFULLY Have students calculate the number of days needed for radon-222 to pass through 5 half-lives and the mass that would remain if a 4.00×10^{-10} g sample was to decay for 5 half-lives. *(19 days; 1.25×10^{-11} g)*

PICTURE DICTIONARY Have students create a picture dictionary of terms they have studied in this chapter. Instruct students to include a definition for each term listed in the Study Guide and a drawing that demonstrates the term.

Math Tune-Up: Nuclear Reactions

Problem	❶ Analyze	❷ Calculate	❸ Evaluate
Plutonium-239 decays by emitting an alpha particle. What is the product of this reaction? $^{239}_{94}\text{Pu} \longrightarrow {}^{4}_{2}\text{He} + \text{X}$	Knowns: mass number of Pu = 239 mass number of α = 4 atomic number of Pu = 94 atomic number of α = 2 Unknowns: Mass number of X = ? Atomic number of X = ? Identity of X = ? In an equation for a nuclear reaction, mass numbers and atomic numbers must be balanced.	The mass number of X must equal the mass number of Pu minus the mass number of α. The atomic number of X must equal the atomic number of Pu minus the atomic number of α. $^{239}_{94}\text{Pu} \longrightarrow {}^{4}_{2}\text{He} + {}^{239-4}_{94-2}\text{X}$ $\longrightarrow {}^{4}_{2}\text{He} + {}^{235}_{92}\text{X}$ The element with atomic number 92 is uranium. $^{239}_{94}\text{Pu} \longrightarrow {}^{4}_{2}\text{He} + {}^{235}_{92}\text{U}$	The mass numbers total 239 on both sides of the equation. The atomic numbers total 94 on both sides of the equation. The isotope uranium-235 is a well-known radioisotope.
Thorium-234 has a half-life of 24.1 days. If a thorium-234 sample has a mass of 6.4×10^{-12} g, how much of the sample is left after 72.3 days?	Knowns: Original mass of Th = 6.4×10^{-12} g Decay time = 72.3 days $t_{\frac{1}{2}}$ = 24.1 days Unknowns: Mass of Th remaining = ? The mass of thorium-234 decreases by half with each half-life. Find the number of half-lives in 72.3 days and multiply the mass of thorium by $\frac{1}{2}$ for each half-life.	Divide the decay time by the half-life of thorium to find the number of half-lives. $\frac{72.3\ \text{days}}{24.1\ \text{days/half-life}} = 3$ half-lives Multiply the mass of thorium by $\frac{1}{2}$ three times. $6.4 \times 10^{-12}\text{ g} \times \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} =$ $8.0 \times 10^{-11}\text{ g}$	After three half-lives, the number of atoms of a radioisotope will decrease to $\frac{1}{8}$ of the original number. Hint: Review Sample Problem 25.1 for another calculation involving half-life.
Carbon-14 undergoes beta decay and produces nitrogen-14. The half-life for this process is 5730 years. In a sample from an ancient piece of pottery, the ratio of carbon-14 atoms to nitrogen-14 atoms is 25%. How old is the pottery?	Knowns: $t_{\frac{1}{2}}$ = 5730 yr Ratio of C-14 to N-14 = 25% Unknown: Age of sample = ? The number of C-14 atoms decreases by half every 5730 years. Find the number of half-lives that reduce the number of C-14 atoms to $\frac{1}{4}$ (25%) and multiply by 5730.	A ratio of C-14 atoms to N-14 atoms of $\frac{1}{4}$ means that C-14 has decayed for two half-lives: $\frac{1}{4} = \frac{1}{2} \times \frac{1}{2} = \left(\frac{1}{2}\right)^2$ Convert two half-lives to years. 5730 years × 2 = 11,460 years	The pottery sample is 11,460 years old, which is equal to two half-lives or the time required for 75% of the carbon-14 atoms to decay.

Focus on ELL

5 ASSESS UNDERSTANDING Use a visually based assessment by choosing one or two diagrams from each lesson and having students explain the content.

BEGINNING:

LOW Ask students yes/no questions about the diagrams.

HIGH Ask students questions that they can answer with one or two words.

INTERMEDIATE: LOW/HIGH Ask students questions that they can answer with one or two simple sentences.

ADVANCED: LOW/HIGH Show each diagram to students and have them explain the content in several sentences.

c. $^{40}_{19}K \longrightarrow {}^{40}_{20}Ca + {}^{0}_{-1}e$

d. $^{13}_{7}N \longrightarrow {}^{13}_{8}O + {}^{0}_{-1}e$

40. **a.** mass number is unchanged; atomic number: increases by 1

b. mass number decreases by 4; atomic number decreases by 2

c. Mass number and atomic number are both unchanged.

41. **a** $^{234}_{92}U$ **b.** $^{206}_{81}Tl$ **c.** $^{206}_{82}Pb$ **d.** $^{226}_{88}Ra$

LESSON 25.2

42. It undergoes radioactive decay.

43. $^{17}_{9}F \longrightarrow {}^{17}_{8}O + {}^{0}_{+1}e$

44. **a.** $^{13}_{6}C$ **b.** $^{1}_{1}H$ **c.** $^{16}_{8}O$ **d.** $^{14}_{7}N$

45. One half-life is the time required for one-half of the atoms of a radioisotope to emit radiation and decay.

46. so the person is exposed to radioactivity for a limited time

47. 0.625 mg

48. Transmutations that occur in nature are natural radioactivity. Transmutations that are forced to occur in reactors or accelerators are artificial radioactivity.

49. The elements with an atomic number greater than 92; none occur in nature and all are radioactive.

LESSON 25.3

50. Nuclear fission occurs when certain isotopes are bombarded with neutrons and split into smaller fragments. In a chain reaction, neutrons emitted during fission bombard other nuclei, which split and emit additional neutrons.

25 Assessment

* Solutions appear in Appendix E

Lesson by Lesson

25.1 Nuclear Radiation

34. Explain how radioisotopes are different from other isotopes.

35. The decay of radium-226 produces an isotope of the element radon and alpha radiation. The atomic number of radium (Ra) is 88; the atomic number of radon (Rn) is 86. Write a balanced equation for this transformation.

***36.** An isotope of the element lead (Pb) decays to an isotope of the element bismuth (Bi) by emission of a beta particle. Complete the equation for the reaction by supplying the missing atomic number and mass number.

$$^{210}_{?}Pb \longrightarrow {}^{?}_{83}Bi + {}^{0}_{-1}e$$

37. Write the symbol and charge for each item.

a. alpha particle
b. beta particle
c. gamma ray

***38.** Alpha radiation is emitted during the decay of the following isotopes. Write balanced nuclear equations to describe each decay process. Name the element produced in each case.

a. uranium-238 ($^{238}_{92}U$)
b. thorium-230 ($^{230}_{90}Th$)
c. uranium-235 ($^{235}_{92}U$)
d. radon-222 ($^{222}_{86}Rn$)

39. The following radioisotopes are beta emitters. Write balanced nuclear equations to describe each decay process.

a. carbon-14 ($^{14}_{6}C$)
b. strontium-90 ($^{90}_{38}Sr$)
c. potassium-40 ($^{40}_{19}K$)
d. nitrogen-13 ($^{13}_{7}N$)

***40.** How are the mass number and atomic number of a nucleus affected by the loss of the following?

a. beta particle
b. alpha particle
c. gamma ray

41. The following radioactive nuclei decay by emitting alpha particles. Write the product of the decay process for each isotope.

a. $^{238}_{94}Pu$
b. $^{210}_{83}Bi$
c. $^{210}_{84}Po$
d. $^{230}_{90}Th$

25.2 Nuclear Transformations

***42.** What happens to an atom with a nucleus that falls outside the band of stability?

43. Write an equation for the radioactive decay of fluorine-17 by positron emission.

44. Identify the more stable isotope in each pair.

a. $^{14}_{6}C$, $^{13}_{6}C$
b. $^{3}_{1}H$, $^{1}_{1}H$
c. $^{15}_{8}O$, $^{16}_{8}O$
d. $^{13}_{7}N$, $^{14}_{7}N$

45. Define *half-life*.

46. Why is it important that radioactive isotopes used for diagnosis or treatment of medical problems have relatively short half-lives?

***47.** A patient is given 20 mg of iodine-131. The half-life of iodine-131 is 8 days. How much of the isotope will remain in the patient's body after 40 days?

48. What is the difference between natural and artificial radioactivity?

49. What are the transuranium elements? Why are they unusual?

25.3 Fission and Fusion

50. Describe the process of nuclear fission, and define a nuclear chain reaction.

51. Why are spent fuel rods removed from a reactor core? What do they contain? What happens to them after they are removed?

52. Fusion reactions produce enormous amounts of energy. Why is fusion not used to generate electrical power?

25.4 Radiation in Your Life

53. Why are X-rays and the radiation emitted by radioisotopes called ionizing radiation?

54. Why must people rely on devices such as Geiger counters to detect radiation?

55. What type of people are required to wear a film badge and what is the purpose of this device?

56. Why are cancer cells more easily damaged by high-energy radiation than healthy cells are?

51. Fuel rods are removed when they can no longer sustain a constant output of electricity. The rods contain the remaining nuclear fuel and fission products. The rods are stored in pools of water.

52. Fusion requires extremely high temperatures, making it difficult to start or contain the reaction.

LESSON 25.4

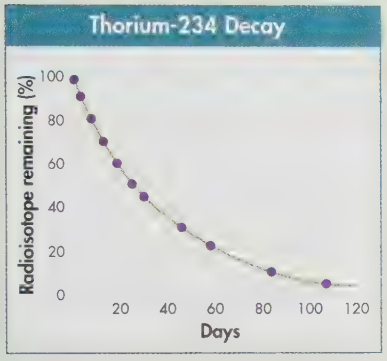
53. Ionizing radiation, such as X-rays and gamma radiation, has sufficient energy to remove electrons from the atoms it hits.

54. Humans cannot use their senses to detect radiation.

55. People who work with or near ionizing radiation must wear a badge to monitor their exposure.

56. Cancer cells grow at a faster rate than do healthy cells.

Understand Concepts



*57. Write balanced nuclear equations for these transmutations.
- a. $^{30}_{15}P$ to $^{30}_{14}Si$
- b. $^{13}_{6}C$ to $^{14}_{6}C$
- c. $^{131}_{53}I$ to $^{131}_{54}Xe$

58. How are the nuclear reactions that take place in the sun different from the nuclear reactions that take place in a nuclear reactor?

59. Complete these nuclear equations.
- a. $^{32}_{15}P \longrightarrow \square + {}^{0}_{-1}e$
- b. $\square \longrightarrow {}^{14}_{7}N + {}^{0}_{-1}e$
- c. $^{238}_{92}U \longrightarrow {}^{234}_{90}Th + \square$
- d. $^{141}_{56}Ba \longrightarrow \square + {}^{0}_{-1}e$
- e. $\square \longrightarrow {}^{181}_{77}Ir + {}^{4}_{2}He$

60. Write nuclear equations for the beta decay of the following isotopes.
- a. $^{90}_{38}Sr$ b. $^{14}_{6}C$ c. $^{137}_{55}Cs$ d. $^{239}_{93}Np$ e. $^{50}_{22}Ti$

61. The graph shows the radioactive decay curve for thorium-234. Use the graph to answer the questions below.

- a. What percentage of the isotope remains after 60 days?
- b. After 40 days have passed, how many grams of a 250-g sample of thorium-234 would remain?
- c. How long would it take in days for 44 g of thorium-234 to decay to 4.4 g of thorium-234?
- d. What is the half-life of thorium-234?

62. Write a balanced nuclear equation for each word equation.
- a. Radon-222 emits an alpha particle to form polonium-218.
- b. Radium-230 is produced when thorium-234 emits an alpha particle.
- c. When polonium-210 emits an alpha particle, the product is lead-206.

63. Briefly describe the contributions the following people made to the study of radioactivity and nuclear chemistry.
- a. Marie Curie
- b. Antoine Henri Becquerel
- c. James Chadwick
- d. Ernest Rutherford

64. How many protons and how many neutrons are in each of the following nuclei?
- a. $^{60}_{27}Co$ b. $^{206}_{82}Pb$ c. $^{233}_{90}Th$ d. $^{3}_{1}H$

*65. A sample of matter has 32 million radioactive atoms. How many of these atoms would be left after five half-lives?

66. Write balanced nuclear equations for alpha emission by each of these isotopes.
- a. $^{231}_{91}Pa$ b. $^{241}_{95}Am$ c. $^{226}_{88}Ra$ d. $^{252}_{99}Es$

*67. Write balanced nuclear equations for beta emission by each of these isotopes.
- a. $^{3}_{1}H$ b. $^{28}_{12}Mg$ c. $^{131}_{53}I$ d. $^{75}_{34}Se$

68. Use the concept of stability to compare chemical reactions with nuclear reactions.

69. The ratio of carbon-14 to carbon-12 in a chunk of charcoal from an archaeological dig is one-half the ratio of carbon-14 to carbon-12 in a piece of freshly cut wood. Hold old is the chunk of charcoal?

70. How are a positron and an electron similar? How are they different?

*71. Use what you know about balanced nuclear reaction equations to complete the following equations.
- a. $^{38}_{19}K \longrightarrow {}^{38}_{20}Ca + ?$
- b. $^{242}_{94}Pu \longrightarrow ? + {}^{4}_{2}He$
- c. $^{68}_{31}Ga \longrightarrow ? + {}^{0}_{-1}e$
- d. $^{68}_{32}Ge \longrightarrow {}^{68}_{31}Ga + ?$

Answers

UNDERSTAND CONCEPTS

57. a. $^{30}_{15}P + {}^{0}_{-1}e \longrightarrow {}^{30}_{14}Si$
- b. $^{13}_{6}C + {}^{1}_{0}n \longrightarrow {}^{14}_{6}C$
- c. $^{131}_{53}I \longrightarrow {}^{131}_{54}Xe + {}^{0}_{-1}e$

58. Nuclear fusion takes place in the sun. A nuclear reactor utilizes nuclear fission.

59. a. $^{32}_{16}S$ b. $^{14}_{6}C$ c. $^{4}_{2}He$ d. $^{141}_{57}La$ e. $^{185}_{79}Au$

60. a. $^{90}_{38}Sr \longrightarrow {}^{90}_{39}Y + {}^{0}_{-1}e$
- b. $^{14}_{6}C \longrightarrow {}^{14}_{7}N + {}^{0}_{-1}e$
- c. $^{137}_{55}Cs \longrightarrow {}^{137}_{56}Ba + {}^{0}_{-1}e$
- d. $^{239}_{93}Np \longrightarrow {}^{239}_{94}Pu + {}^{0}_{-1}e$
- e. $^{50}_{22}Ti \longrightarrow {}^{50}_{23}V + {}^{0}_{-1}e$

61. a. about 20% c. about 83 days
- b. about 85 g d. about 25 days

62. a. $^{222}_{86}Rn \longrightarrow {}^{218}_{84}Po + {}^{4}_{2}He$
- b. $^{234}_{90}Th \longrightarrow {}^{230}_{88}Ra + {}^{4}_{2}He$
- c. $^{210}_{84}Po \longrightarrow {}^{206}_{82}Pb + {}^{4}_{2}He$

63. a. coined the term radioactivity and did pioneering work with Becquerel
- b. discovered natural radioactivity from uranium ores
- c. discovered the neutron
- d. performed the first artificial transmutation

64. a. 27 protons and 33 neutrons
- b. 82 protons and 124 neutrons
- c. 90 protons and 143 neutrons
- d. 1 proton and 2 neutrons

65. 1 million atoms

66. a. $^{231}_{91}Pa \longrightarrow {}^{227}_{89}Ac + {}^{4}_{2}He$
- b. $^{241}_{95}Am \longrightarrow {}^{237}_{93}Np + {}^{4}_{2}He$
- c. $^{226}_{88}Ra \longrightarrow {}^{222}_{86}Rn + {}^{4}_{2}He$
- d. $^{252}_{99}Es \longrightarrow {}^{248}_{97}Bk + {}^{4}_{2}He$

67. a. $^{3}_{1}H \longrightarrow {}^{3}_{2}He + {}^{0}_{-1}e$
- b. $^{28}_{12}Mg \longrightarrow {}^{28}_{13}Al + {}^{0}_{-1}e$
- c. $^{131}_{53}I \longrightarrow {}^{131}_{54}Xe + {}^{0}_{-1}e$
- d. $^{75}_{34}Se \longrightarrow {}^{75}_{35}Br + {}^{0}_{-1}e$

68. In chemical reactions, the transfer or sharing of electrons may make atoms more stable. In nuclear reactions, changes in their nuclei make atoms of unstable isotopes more stable.

69. 5730 years

70. A positron and an electron have the same mass but opposite charges.

71. a. $^{0}_{+1}e$ b. $^{238}_{92}U$ c. $^{68}_{32}Ge$ d. $^{0}_{-1}e$

Evaluate

Answers

THINK CRITICALLY

72 **a.** platinum **e.** xenon
b. thorium **f.** californium
c. francium **g.** vanadium
d. titanium **h.** palladium.

Thorium (b), francium (c), and californium (f) have no stable isotopes.

73. Zirconium-90 and neon-21 nuclei are stable; neodymium-130 nuclei are unstable.

74. In every round of the tournament, one-half the teams are eliminated; in every half-life, one-half the nuclei decay. In the tournament a single team eventually emerges as the winner and the tournament stops, but radioactive decay continues (almost) indefinitely.

75. $^{215}_{85}\text{At}$

76. 11,460 years

77. The large mass of the alpha particle and its charge make it more likely that it will collide with another particle and be stopped.

78. Radioactive isotopes of these elements can be incorporated into the body tissues of organisms. When the isotopes decay, they can damage cells within tissues.

79. The treatment dose is larger than the dose used for detection.

80. No, because the detector would not be effective after a relatively short period of time

81. one neutron

82. $^{25}_{12}\text{Mg}$

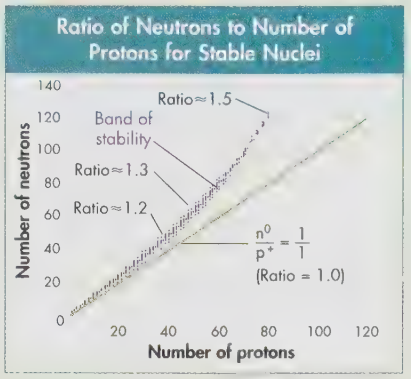
83. uranium; $^{239}_{94}\text{Pu} \longrightarrow {}^{235}_{92}\text{U} + {}^{4}_{2}\text{He}$

84. 24.6 years

85. The combination of half-life and type of radiation emitted is unique for each isotope.

86. The discovery of radioactivity contradicted Dalton's assumption that atoms of one element are never changed into atoms of another element.

87. $^{18}_{8}\text{O}$



88. Toppling one domino leads to the fall of other dominoes just as the emission of neutrons by one fissionable atom leads to the emission of more neutrons and more fission.

Think Critically

***72.** **Classify** Name the elements represented by the following symbols and indicate which of them would have no stable isotopes.

a. Pt **b.** Th **c.** Fr **d.** Ti
e. Xe **f.** Cf **g.** V **h.** Pd

73. **Interpret Graphs** Use the graph to determine which of these isotopes have stable nuclei: neon-21, zirconium-90, and neodymium-130.

74. **Use Analogies** Compare the half-life of an element to a single-elimination sports tournament. *Hint:* What happens in each round of the tournament?

75. **Infer** A radioactive nucleus decays to give a bismuth-211 ($^{211}_{83}\text{Bi}$) nucleus and an alpha particle. What was the original nucleus?

***76.** **Calculate** The carbon-14 content of an object produces 4 counts per minute per gram of carbon. Living matter has a carbon-14 content that produces 16 counts per minute per gram of carbon. What is the age of the object?

77. **Relate Cause and Effect** Why is an alpha particle less penetrating than a beta particle?

78. **Infer** Why might radioisotopes of C, N, and O be especially harmful to living creatures?

79. **Compare and Contrast** Iodine-131 is used to diagnose and treat thyroid disorders. What is the main difference between the two processes?

80. **Apply Concepts** Should a radioisotope with a half-life measured in days be used in a smoke detector? Why or why not?

81. **Calculate** Bismuth-209 was bombarded with iron-58 for several days. Meitnerium ($^{266}_{109}\text{Mt}$) was produced. How many neutrons were released per atom?

$$^{209}_{83}\text{Bi} + {}^{58}_{26}\text{Fe} \longrightarrow {}^{266}_{109}\text{Mt} + ?{}^{1}_{0}\text{n}$$

***82.** **Predict** When neutrons strike magnesium-24 ($^{24}_{12}\text{Mg}$), a neutron is captured and photons are ejected. What new element is formed?

83. **Make Generalizations** Plutonium-239 emits alpha particles, which do not penetrate a thin sheet of paper or skin. Under what conditions would plutonium-239 be especially hazardous for organisms?

***84.** **Calculate** Tritium (hydrogen-3) has a half-life of 12.3 years. How old is a bottle of wine if the tritium content is 25% that of new wine?

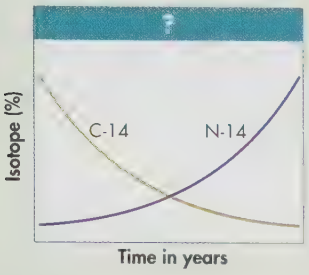
85. **Apply Concepts** What properties of isotopes make it possible to use neutron activation analysis to identify the composition of matter?

86. **Relate Cause and Effect** What effect did the discovery of radioactivity have on Dalton's model of the atom?

87. **Analyze Data** A sample of californium-249 ($^{249}_{98}\text{Cf}$) was used as the target in the synthesis of seaborgium ($^{236}_{106}\text{Sg}$). Four neutrons were emitted for each transformed $^{249}_{98}\text{Cf}$. The result was a nucleus with 106 protons and a mass of 263 amu. What type of particle struck the target?

$$^{249}_{98}\text{Cf} + ? \longrightarrow 4{}^{1}_{0}\text{n} + {}^{263}_{106}\text{Sg}$$

88. **Use Models** Explain how the falling dominoes in the photograph can be used as a model for a chain reaction.



Enrichment

89. **Calculate** The radioisotope cesium-137 has a half-life of 30 years. A sample decayed at the rate of 544 counts per minute in the year 1985. In what year will the decay rate be 17 counts per minute?

90. **Interpret Graphs** Use the graph below to answer the questions.

a. Describe the process that is being depicted in the graph.

b. Suggest an appropriate title for the graph.

91. **Apply Concepts** Bismuth-211 decays by alpha emission to yield another radioisotope, which emits beta radiation as it decays to a stable isotope. Write equations for the nuclear reactions and name the decay products.

92. **Analyze Data** What isotope remains after three beta particles and five alpha particles are lost from a thorium-234 isotope?

93. **Evaluate** In the following argument, the third statement is based on the first two statements. Is the reasoning logical? Why or why not?

(1) Radiation kills fast-growing cells.
(2) Cancer cells are fast-growing.
(3) Therefore, radiation kills only cancer cells.

***94.** **Calculate** Uranium has a density of 19 g/cm^3. What volume does a mass of 8.0 kg of uranium occupy?

95. **Make Generalizations** Element 107 (Bh) is formed when nuclei of element 109 (Mt) each emit an alpha particle. Nuclei of element 107, in turn, each emit an alpha particle, forming an atom with a mass number of 262. Write balanced equations for these two nuclear reactions.

Write About Science

96. **Summarize** Research methods used to date materials such as pottery, coral, and stone. Prepare a written report that summarizes your findings on the radioisotopes used, their half-lives, and their limitations.

97. **Explain** Research how technetium-99m is produced. What does the letter *m* at the end of its name stand for? How is the isotope used in bone imaging?

CHEMYSTERY

An Ice-Age Baby

Scientists were able to use carbon-14 dating to determine the age of the baby mammoth discovered in 2007. During Lyuba's short time on Earth, the ratio of carbon-14 to other carbon isotopes in her body was constant. After she died, the unstable carbon-14 atoms began to decay. The ratio of carbon-14 atoms to other carbon atoms was no longer fixed. Based on the ratio of carbon isotopes in the preserved sample, Lyuba lived and died about 40,000 years ago.

Archaeologists use the same method to date artifacts left behind by ancient cultures. An artifact is an object made or shaped by humans. Examples of artifacts are tools, weapons, and ornaments.

98. **Calculate** Approximately how many half-lives does 40,000 years represent? The half-life for carbon-14 is 5730 years.

99. **Apply Concepts** Archaeologists find a wooden bowl, a stone arrowhead, and a bone bead at a site that they suspect is about 40,000 years old. Which object can they use to test their hypothesis? Explain.

100. Connect to the **BIG IDEA** Describe what happens to the structure of carbon-14 atoms as this isotope decays.

CHEMYSTERY

APPLY CONCEPTS After students have read through the CHEMystery, discuss with students how scientists used a knowledge of nuclear reactions to determine when Lyuba lived. **Ask** What type of nuclear reaction is used in carbon-14 dating? *(radioactive decay)* **Ask** Did the fact that Lyuba was found frozen in ice affect the decay of the carbon-14? *(No. Radioactive decay does not depend on temperature.)*

Then, have students consider how the type of item to be dated determines what isotope a scientist uses to determine the item's age. **Ask** Suppose the reindeer herder who found Lyuba had instead found a rock with the imprint of a fossil that appeared extremely old. Could carbon-14 dating have been used to determine the age of the imprint? Explain. *(No. Carbon-14 dating is useful only for dating once-living things.)* Note that, because the half-life of carbon-14 is 5730 years, it can only be used for dating objects up to about 60,000 years old.

CHEMYSTERY ANSWERS

98. about 7 half-lives

99. They can use either the bowl or the bead because the material in both objects came from a once-living organism.

100. A neutron in the carbon-14 nucleus splits into a proton and an electron. The proton remains in the nucleus; the electron is emitted as a beta particle.

ASSESSMENT

Answers

ENRICHMENT

89. 2135

90. **a.** the radioactive (beta) decay of carbon-14, along with the increase of the nitrogen product

b. Effect of Time on Carbon-14 and Nitrogen-14 Concentrations

91. $^{211}_{83}Bi \longrightarrow {}^{207}_{81}Tl + {}^{4}_{2}He$; thallium–207
$^{207}_{81}Tl \longrightarrow {}^{207}_{82}Pb + {}^{0}_{-1}e$; lead–207

92. Bismuth-214 remains.

93. The reasoning is not sound. Cells other than cancer cells may be fast-growing and therefore killed by radiation as well.

94. 94.2×10^2 cm^3

95. $^{268}_{109}Mt \longrightarrow {}^{264}_{107}Bh + {}^{4}_{2}He$
$^{264}_{107}Bh \longrightarrow {}^{262}_{105}Db + {}^{4}_{2}He$

WRITE ABOUT SCIENCE

96. Students should note that the half-life of an isotope can limit its usefulness for dating certain objects.

97. Tc-99m is made from the decay of molybdenum-99, which also has a relatively short half-life. The *m* means "metastable," which indicates that the isotope might become more or less stable. Medical uses might include the following examples. To pinpoint a liver problem, doctors inject a mixture containing Tc-99m, which should be absorbed by the liver. If gamma radiation emitted by the Tc-99m atoms in the mixture is detected in the kidneys, there is likely a problem with the liver. If the mixture reaches the liver but does not reach the gallbladder, the duct connecting the organs is probably blocked. Tc-99m is also used to detect the presence of cancerous cells in bone marrow.

ASSESSMENT

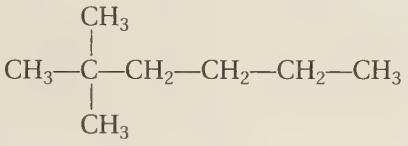
Cumulative Review

101. **a.** 26 protons and 33 neutrons
b. 92 protons and 143 neutrons
c. 24 protons and 28 neturons

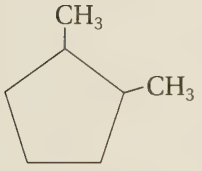
102. The Pauli exclusion principle states that no two electrons in an atom can have the same quantum numbers. Hund's rule states that electrons that occupy orbitals of equal energy distribute with unpaired spins as much as possible.

103. **a.** covalent **b.** ionic **c.** covalent **d.** ionic



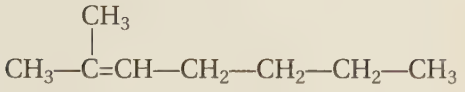
104. The oxygen atom carries a partial negative charge, and the hydrogen atoms carry partial positive charges. The water molecule's bent shape results in a net polarity, and the negative end of one molecule attracts the positive end of another molecule.

105. $9.22 \times 10^3\ cm^3\ H_2$; 0.412 mol H_2



106. **a.** $Ca(OH)_2 + 2HCl \rightarrow CaCl_2 + 2H_2O$
b. $Fe_2O_3 + 3H_2 \rightarrow 2Fe + H_2O$
c. $2NaHCO_3 + H_2SO_4 \rightarrow Na_2SO_4 + 2CO_2 + 2H_2O$
d. $2C_2H_6 + 7O_2 \rightarrow 4CO_2 + 6H_2O$

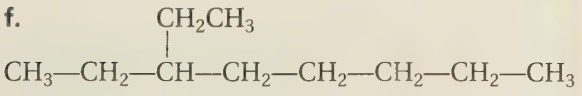
107. 6.7 mL



108. **a.**

b.

c.



d. $CH_3—C{\equiv}C—CH_3$

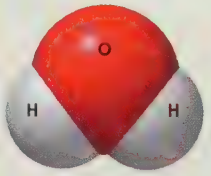
e.

f.

109. **a.** propanoic acid **b.** propanal **c.** 1-propanol **d.** 1-aminopropane **e.** 1-chloropropane **f.** ethylmethyl ether

110. **a.** ethanal **b.** ethene **c.** ethanoic acid **d.** ethyne

111. 1-propanol and ethanoic acid



Cumulative Review

101. How many protons, neutrons, and electrons are in an atom of each isotope?
a. iron-59
b. uranium-235
c. chromium-52

102. What is the Pauli exclusion principle? What is Hund's rule?

103. Identify the bonds between each pair of atoms as ionic or covalent.
a. carbon and silicon
b. calcium and fluorine
c. sulfur and nitrogen
d. bromine and cesium

104. The diagram below shows a water molecule. Identify the location of any partial positive and partial negative charges on the molecule. Then explain how the partial charges and their locations produce an attraction between different water molecules.

***105.** A piece of magnesium with a mass of 10.00 g is added to sulfuric acid. How many cubic centimeters of hydrogen gas (at STP) will be produced if the magnesium reacts completely? How many moles of hydrogen gas are in this volume?

106. Balance the following equations.
a. $Ca(OH)_2 + HCl \longrightarrow CaCl_2 + H_2O$
b. $Fe_2O_3 + H_2 \longrightarrow Fe + H_2O$
c. $NaHCO_3 + H_2SO_4 \longrightarrow Na_2SO_4 + CO_2 + H_2O$
d. $C_2H_6 + O_2 \longrightarrow CO_2 + H_2O$

***107.** You have a 0.30*M* solution of sodium sulfate. What volume (in mL) must be measured to give 0.0020 mol of sodium sulfate?

108. Draw the structural formula for each compound.
a. 2,2-dimethylhexane
b. 1,2-dimethylcyclopentane
c. 2-methyl-2-heptene
d. 2-butyne
e. 1,4-dimethylbenzene
f. 3-ethyloctane

109. Name each compound.
a. CH_3CH_2COOH
b. CH_3CH_2CHO
c. $CH_3CH_2CH_2OH$
d. $CH_3CH_2CH_2NH_2$
e. $CH_3CH_2CH_2Cl$
f. $CH_3CH_2OCH_3$

110. For each pair of compounds, which is the more highly oxidized?
a. ethanol and ethanal
b. ethane and ethene
c. ethanoic acid and ethanal
d. ethyne and ethane

111. What two compounds result from the acid-catalyzed hydrolysis of propyl ethanoate?

112. Which of these classes of compounds does not contain a carbon–oxygen double bond?
a. amide
b. ketone
c. aldehyde
d. carboxylic acid

113. Match a numbered item with each term.

a. amino acid	**(1)** carbohydrate
b. fat	**(2)** nucleic acid
c. monosaccharide	**(3)** lipid
d. peptide bond	**(4)** protein
e. sugar	
f. DNA	
g. saponification	
h. genetic code	
i. enzyme	
j. triglyceride

Standard: C.2.8

Tips for Success

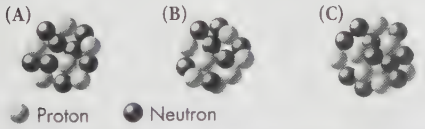
Anticipate the Answer Use what you know to decide what you think the answer should be. Then see if your answer, or one similar to it, is given as a choice.

Select the choice that best answers each question.

1. If a radioisotope undergoes beta emission,
   (A) the atomic number changes.
   (B) the number of neutrons remains constant.
   (C) the isotope loses a proton.
   (D) the mass number changes.

2. The radioisotope radon-222 has a half-life of 3.8 days. How much of an initial 20.0-g sample of radon-222 would remain after 15.2 days?
   (A) 5.00 g (C) 1.25 g
   (B) 12.5 g (D) 2.50 g

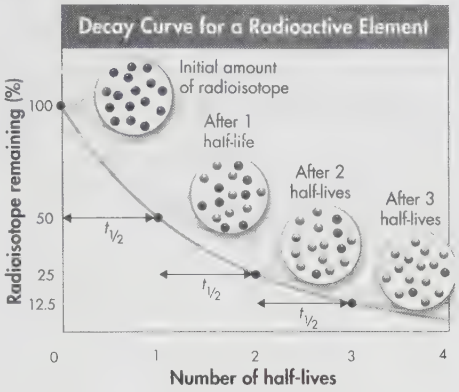
3. Spent fuel rods from nuclear reactors
   (A) are no longer radioactive.
   (B) are stored under water for at least a decade.
   (C) contain only one isotope of uranium, ^{238}U.
   (D) remain radioactive for less than 100 years.



4. What particle is needed to balance this equation?
   $^{27}_{13}Al + {}^{4}_{2}He \longrightarrow ? + {}^{30}_{15}P$

For each nuclear equation in Questions 5–8, name the particle that is being emitted or captured.

5. $^{59}_{26}Fe \longrightarrow {}^{59}_{27}Co + {}^{0}_{-1}e$
6. $^{185}_{79}Au \longrightarrow {}^{181}_{77}Ir + {}^{4}_{2}He$
7. $^{59}_{27}Co + {}^{1}_{0}n \longrightarrow {}^{60}_{27}Co$
8. $^{118}_{54}Xe \longrightarrow {}^{118}_{53}I + {}^{0}_{+1}e$



Use the drawings of atomic nuclei to answer Questions 9 and 10.

9. Write the name and symbol for each isotope.
10. Which isotope is radioactive?

Use the graph to answer Questions 11–13.

Estimate the percent remaining of the radioisotope after the given number of half-lives.

11. 0.5 $t_{1/2}$
12. 1.25 $t_{1/2}$
13. 3.75 $t_{1/2}$

The lettered choices below refer to Questions 14–17. A lettered choice may be used once, more than once, or not at all.

(A) film badge
(B) radioactive tracer
(C) radiation therapy
(D) neutron activation analysis
(E) Geiger counter

Which of the above items or processes is best described by each of the following applications?

14. treating some cancers
15. detecting ionizing radiation
16. monitoring exposure to radiation
17. diagnosing some diseases

Contents

The Elements Handbook provides information that has traditionally been included within the text in a descriptive chemistry chapter. Beginning on page R2, the information in the handbook is organized by groups of elements. For most groups, there is a two-page spread that contains bulleted lists of properties. The data is divided into categories for easy access. A property spread also supplies information on sources of elements, a reminder of where a group fits into the periodic table, and data on the discovery of elements.

For most groups, there is a two-page spread that contains short articles about specific elements. The articles assume knowledge of the appropriate concepts from the text. How much background students will need depends on the topic. Students could read *Gold* on page R40 early in the year and understand most of the content, but *Swimming Pool Chemistry* on page R30 would be more challenging. The experience would be like reading an article in a newspaper that contains some unfamiliar terms and concepts. The articles are meant to introduce topics without attempting to cover all possible aspects of a topic. For many articles, you will find additional background in the TE wrap.

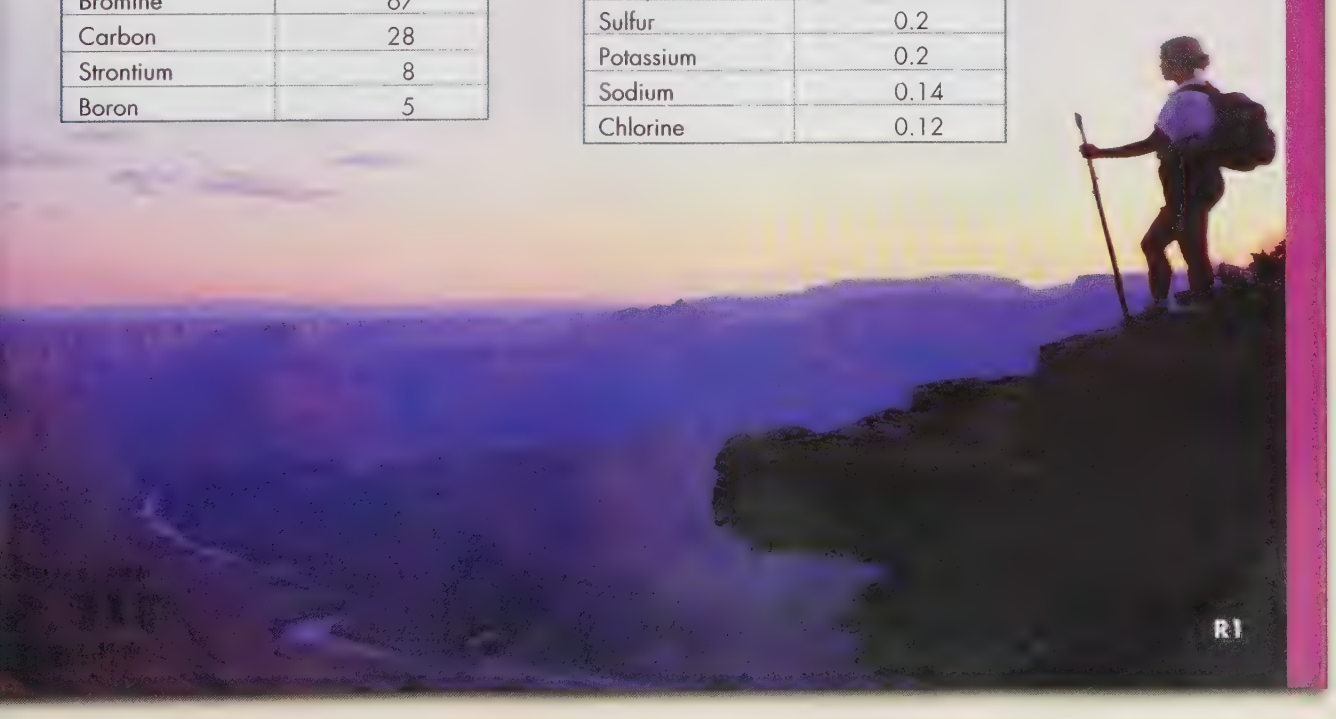
Elements in Earth's Crust

Element	Parts per million
Oxygen	466,000
Silicon	277,000
Aluminum	82,000
Iron	41,000
Calcium	41,000
Sodium	23,000
Potassium	21,000
Magnesium	21,000
Titanium	4400
Hydrogen	1400

Elements in the Atmosphere

Element	Parts per million*
Nitrogen	780,900
Oxygen	209,500
Argon	9300
Neon	18
Helium	5.2
Krypton	1.14
Hydrogen	0.5
Xenon	0.086
Radon	Traces



*Data is for dry air.

Elements Dissolved in the Oceans

Element	Parts per million
Chlorine	19,400
Sodium	10,800
Magnesium	1300
Sulfur	904
Calcium	411
Potassium	392
Bromine	67
Carbon	28
Strontium	8

Oxygen	61
Carbon	23
Hydrogen	10
Nitrogen	2.6
Calcium	1.4
Phosphorus	1.1
Sulfur	0.2
Potassium	0.2
Sodium	0.14
Chlorine	0.12

Elements Around You

To Do

If students total the data in the tables, they will discover that the parts per million for elements in Earth's crust, elements dissolved in the oceans, and elements in the atmosphere add up to 977,800 ppm, 33,315 ppm, and 999,725 ppm, respectively. Students should be able to figure out that the discrepancy in the first and last categories are due to missing data on additional elements. The large discrepancy in the data for the oceans may seem puzzling at first, until students recall that a solution requires a solvent.

Elements Within You

After students study Chapter 24, they should be able to offer an informed explanation for the distribution of elements in the human body. For example, they can note the presence of nitrogen in proteins and nucleic acids, and the presence of phosphorus in nucleic acids, phospholipids, and the molecules that capture and store energy.

Group 1A

The meaning of the term *discovery* can vary because scientists sometimes knew that an element existed, and had named the element, long before the element could be isolated from its compounds. For example, Arfvedson discovered lithium during an analysis of ore containing $LiAl(Si_2O_5)_2$, but lithium was not isolated until W.T. Brande and Sir Humphrey Davy performed an electrolysis of lithium oxide.

Physical Properties

It isn't always easy to establish the melting point or boiling point for a substance. Energy added to a sample to cause a change of state can cause other changes. For example, a melting point cannot be determined for sucrose because it decomposes when heated. It is possible to melt iodine, but not at atmospheric pressure because at that pressure iodine will sublime. To determine the melting point of diamond, the sample must be heated in an inert atmosphere. Otherwise it reacts with oxygen in the air. Even in an inert atmosphere, it is not possible to determine a melting point for graphite because the graphite sublimes.

To Do

To see how physical properties change across the periods in the periodic table, students can compare the ranges on the *y*-axes of the melting and boiling point graphs and the density graphs for Groups 1A–8A.

GROUP 1A

Lithium discovered in 1817 by Johan August Arfvedson

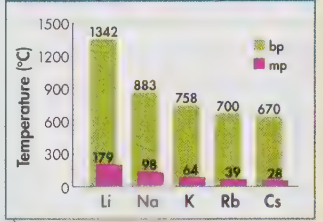
Sodium discovered in 1807 by Sir Humphry Davy

Potassium discovered in 1807 by Sir Humphry Davy

Rubidium discovered in 1861 by Robert Bunsen & Gustav Kirchhoff

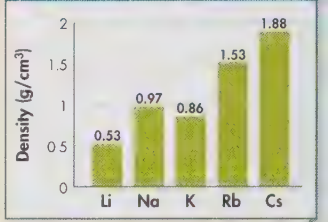
Cesium discovered in 1860 by Robert Bunsen & Gustav Kirchhoff

Francium discovered in 1939 by Marguerite Perey



Physical Properties

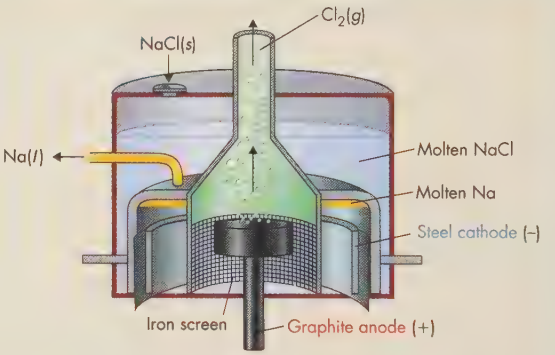
- Alkali metals are silver-gray solids that are soft enough to cut with a knife. They are soft because they have only one valence electron.
- The presence of a single valence electron also explains the low melting points and boiling points of alkali metals.



Pure alkali metals are stored under oil because they will react with oxygen and moisture in air.

Melting and Boiling Points

Density



Sources

- Alkali metals do not occur uncombined in nature because they are highly reactive.
- Sodium occurs widely as sodium chloride in underground salt and brine deposits. It is a major component of seawater.
- Sodium is the only alkali metal manufactured on a large scale. It is generally produced by the electrolysis of molten sodium chloride.

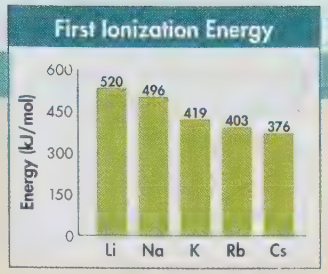
  $2NaCl(l) \longrightarrow 2Na(l) + Cl_2(g)$

  Lithium and potassium are produced by a similar process.
- The mineral sylvite, KCl, is a source of potassium.

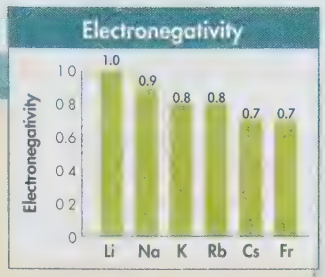
Manufacture of Sodium

R2 Elements Handbook

Sources



As new sources are discovered, the relative abundance of an element may need to be revised. For example, rubidium is now considered more abundant in Earth's crust than zinc or copper. However, there is little market demand for rubidium. Uses for rubidium include fiber optics, night-vision devices, PET scans, and photoelectric cells. Some rubidium is produced as a by-product of processing lithium and cesium ores.



To Do

Some students may want to research how rubidium atoms have been used to produce a Bose-Einstein condensate at a temperature only a few billionths of a degree above absolute zero.

Atomic Properties

- Alkali metals have an electron configuration that ends in ns^1.
- The alkali metals are the most reactive metals.
- Alkali metals form ions with a 1+ charge.
- The atoms of alkali metals are the largest in their periods.
- Cesium is a good reducing agent because its first ionization energy is very low.

	Li	Na	K	Rb	Cs
Atomic radius (pm)	156	191	238	255	273
Ionic radius (pm)	60 Li^+	95 Na^+	133 K^+	148 Rb^+	169 Cs^+

Alkali metals can be identified by the colors produced when their compounds are heated in a flame.

Important Compounds and Reactions

- All alkali metals react with water to form an alkaline solution. Example:

  $2K(s) + 2H_2O(l) \longrightarrow 2KOH(aq) + H_2(g)$

- All alkali metals react with halogens to form an ionic halide. Example:

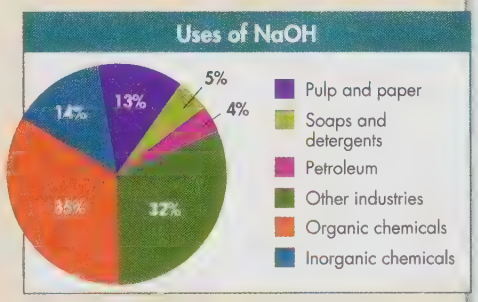
  $2Cs(s) + Cl_2(g) \longrightarrow 2CsCl(s)$

  $\Delta H = -442.8$ kJ/mol

- When heated, sodium hydrogen carbonate (baking soda) produces $CO_2(g)$ and steam, which causes baked goods to rise.

  $2NaHCO_3(s) \xrightarrow{\Delta} Na_2CO_3(s) + CO_2(g) + H_2O(g)$

  $\Delta H = 129$ kJ/mol



- Lithium hydride is a convenient source for preparing hydrogen.

  $LiH(s) + H_2O(l) \longrightarrow LiOH(aq) + H_2(g)$

- Potassium superoxide, KO_2, is a source of oxygen in submarines. It removes CO_2 from the atmosphere as it produces oxygen.

  $4KO_2(s) + 2CO_2(g) \longrightarrow 2K_2CO_3(s) + 3O_2(g)$.

- Sodium hypochlorite, NaClO, is used as a bleach and to disinfect swimming pools.
- Sodium hydrogen carbonate, $NaHCO_3$, is used in fire extinguishers.
- Potassium nitrate, KNO_3, is used in matches and chemical fertilizers.
- Sodium hydroxide, NaOH, is used as a drain cleaner. It is also used to produce other chemicals and in many industrial processes.

GROUP 1A

Atomic Properties

The source for most of the atomic radii data is *Bonding and Structure* by N. W. Alcock (Ellis Horwood, 1999).

Of all elements with atomic numbers between 1 and 100, atoms of francium are the least stable. The longest-lived isotope of francium, francium-233, has a half-life of only 22 minutes.

To Do

Comparing the ranges on the *y*-axes of the first ionization energy graphs for Groups 1A–8A provides another way to emphasize the variation of properties across periods in the periodic table.

Important Compounds and Reactions

To Do

The U.S. chemical industry produces large amounts annually (by mass) of sulfuric acid, phosphoric acid, ammonia, sodium hydroxide, nitric acid, ammonium nitrate, hydrogen chloride, and ammonium sulfate. As a long-term class project, students could collect data from the Elements Handbook and other sources to explain this production.

When students study organic chemistry, they could do similar research on ethylene, propylene, ethylene dichloride, urea, ethylbenzene, styrene, ethylene oxide, cumene, and 1,3-butadiene.

Group 1A

Na Vapor Lamps

mercury to a sodium vapor lamp helps with the problem of color recognition because of the strong blue and green lines in mercury's emission spectrum. However, because the tubes contain mercury, used lamps must be handled according to the rules of disposal for hazardous wastes or the tubes must be recycled.

The sodium vapor in a lamp can be at low pressure or at high pressure. Low-pressure sodium vapor lamps that do not contain mercury cause the least light pollution and are less likely to interfere with astronomical observations.

Because sodium vapor can etch glass, the tube in a sodium vapor lamp is made from a very pure form of aluminum oxide (Al_2O_3) called polycrystalline alumina (PCA). PCA doesn't react with the sodium, and it allows light to pass through.

To Do

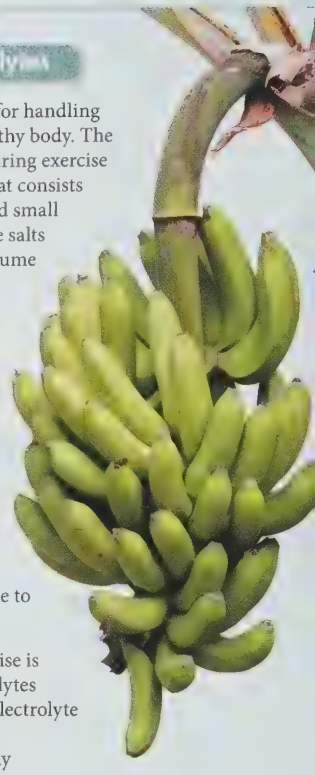
Students could collect data on the background colors and the color of lettering used for traffic signs (e.g., stop, yield, wrong way, and do not enter signs; speed limits and mileposts; parking and construction signs; and information on local tourist attractions). Then students could consider how a sodium vapor lamp might affect the visibility of the signs.

GROUP 1A

Na Vapor Lamps

When streetlights have a golden glow, the source of the light is probably sodium vapor. Inside the lamp is a sealed tube containing a sodium-mercury alloy and a starter gas, such as xenon. Electrodes at each end of the tube are connected to an electric circuit. When the lamp is on, a spark, or arc, forms between the electrodes. The arc produces enough heat to vaporize the sodium and mercury atoms. Within the arc, atoms ionize. Outside the arc, ions recombine with electrons and light is emitted—yellow for sodium and blue-green for mercury.

A sodium vapor lamp uses less energy than most other light sources and costs less to operate. But the lamp isn't a perfect light source. The color of an object is visible only when light of that color is reflected off the object. So yellow lines on the pavement appear yellow under a sodium vapor lamp, but a red stop sign appears gray.



People who grow plants under artificial light may use sodium vapor lamps to stimulate the production of flowers and fruits. The vapor lamps must be combined with other light sources. Otherwise, the plant stems will be too weak to support the plants.

Na K Restoring Electrolytes

"Don't sweat it" may be good advice for handling stress, but not for maintaining a healthy body. The sweat you produce on a hot day or during exercise cools your body as it evaporates. Sweat consists mainly of water, sodium chloride, and small amounts of other inorganic salts. The salts are electrolytes that help keep the volume of body fluids constant. Electrolytes produce ions when they dissolve in water.

Body fluids contain sodium ions and potassium ions. Potassium ions are the principal cations inside cells. Sodium ions are the principal cations in the fluids outside of cells. The transmission of nerve impulses depends on the movement of sodium and potassium ions across the membranes of nerve cells. Potassium ions cause the heart muscle to relax between heartbeats.

Replacing the water lost during exercise is important, but not sufficient. Electrolytes must be replaced too. Some signs of electrolyte depletion are muscle cramps, nausea, and an inability to think clearly. Many athletes use sports drinks to replace electrolytes. Some experts recommend these drinks for people who lose more than 8 liters of sweat daily or exercise continuously for more than 60 minutes.

Bananas account for about one-third of the fresh fruit consumed in the United States.

Table salt is the chief source of sodium in the diet. But large amounts are also found in unexpected places, such as eggs. For a healthy adult, the recommended daily intake of sodium chloride is about 5 grams per day—about half the amount many people consume. The daily recommended amount of potassium is about 1 gram. The word *daily* is important because your kidneys excrete potassium even when the supply is low. Eating foods high in potassium and low in sodium is ideal. Such foods include bananas, chicken, and orange juice.

R4 Elements Handbook

Na K Restoring Electrolytes

To Do

Relying more on fresh foods than processed foods can reduce the total amount of sodium chloride in a person's diet. Students could look at the labels for some processed foods and compare the sodium chloride content.

Students might also want to estimate how much sodium chloride they ingest daily from processed foods. Remind them that this quantity is in addition to the sodium chloride that is present in unprocessed foods.

Cs Cesium Atomic Clock

Some watches contain a quartz crystal that vibrates at a constant rate. The vibration provides the "beat" that is translated into the time you see displayed. A clock with a quartz crystal is more accurate than a mechanical clock, which has moving parts that can be worn down by friction. But a quartz crystal isn't accurate enough for modern communication and navigation systems.

For greater accuracy, you need an atomic clock, which may gain or lose only one second in a million years! In most atomic clocks, cesium-133 atoms provide the "beat." Unlike quartz crystals, all cesium-133 atoms are identical and they don't wear out with use. The clock is designed so that the atoms repeatedly absorb and emit radiation. The emitted radiation has a frequency of exactly 9,192,631,770 cycles per second. The cycles are counted and translated into seconds, minutes, and hours.

There are four cesium atomic clocks at the National Institute of Standards and Technology in Fort Collins, Colorado. Short-wave radio waves are useds to transmit accurate time signals from these clocks to most of North America. Clocks and watches advertised as "radio controlled" contain a tiny antenna and receiver that pick up the signal and decode the information. The owner sets the time zone. The radio signal sets the time.

Global Positioning System (GPS) receivers can pinpoint any location on Earth to within a few meters. The system depends on accurate time signals from atomic clocks in 24 Earth-orbiting satellites.

The GPS receiver in this car compares signals sent at exactly the same time from three different satellites to determine a location.

Na Salt of the Earth

In the ancient world, table salt (NaCl) was an extremely valuable commodity. Before refrigeration, salt was used to preserve foods such as meats and fish. As salt draws the water out of bacteria, they shrivel up and die. Sailors ("salty dogs") especially depended on salt pork and fish to survive long voyages.

Trade routes were established and roads were built to transport salt. In ancient China, coins were made of salt and taxes were levied on salt. Roman soldiers were paid an allotment called a *salarium argentum*, or "salt silver," from which the word *salary* is derived.

Li Bipolar Disorder

Millions of people in the United States experience the extreme mood swings of bipolar disorder. During a manic phase, they think they can conquer the world. During a depression, they may feel hopeless. The ionic compound lithium carbonate can be used to control these symptoms.

Exactly how the treatment works is not known. Scientists do know that lithium ions can increase the level of serotonin. Serotonin is one of the chemical messengers (neurotransmitters) that transmit messages between brain cells.

Did You Know?

Most alkali metals are stored under oil. But **lithium** has such a low density that it floats on oil. So a coat of petroleum jelly is applied to lithium before it is stored.

Li Bipolar Disorder

Dr. John Cade discovered the mood-altering effect of lithium ions in 1949. His discovery had a major impact on the field of psychiatry. Up to that point, the accepted view was that mental health problems were always psychological. Talk therapy was the approved method of treatment. But many patients did not respond to this approach. Dr. Cade's work demonstrated that a mental illness could be caused by the wrong amount of a chemical in the body.

In the case of depression, the chemical in question is serotonin, which is manufactured in the brain. Scientists agree that a serotonin deficiency and depression are related. The level of serotonin in the blood is lower in people who are diagnosed with depression. What scientists have not yet determined is whether the decrease in serotonin is a cause or a symptom of depression.

Cs Cesium Atomic Clock

A quartz crystal can keep accurate time to about one second every ten years. Over time, the vibrations of the crystal are affected by changes in temperature, impurities in the crystal, and the accumulated effects of the vibrations.

In a cesium clock, the valence electron in a cesium-133 atom oscillates between two hyperfine states. In one state, the magnetic field of the valence electron is in the same direction as the magnetic field of the nucleus. In the other state, the magnetic field is in the opposite direction.

GPS satellites transmit data that indicates their location and current time. 24 satellites are operating at all times with 3 satellites in reserve. Signals that are released simultaneously from different satellites will arrive at a receiver at slightly different times. A minimum of three satellites is needed. Using additional satellites increases the precision of the data.

To Do

Ask students to interpret the following statement. A person with one watch knows the time very well, but a person with two watches is not so certain.

Na Salt of the Earth

A good person is sometimes described as the "salt of the earth" and an unworthy person as "not worth his salt," or not worth the wages he receives.

In non-industrial countries, the principal use of NaCl is still food preparation and preservation. In the United States, 40% of NaCl is used for the production of chlorine and sodium hydroxide, and another 40% in de-icing roads. Table salt accounts for only 1% of usage.

Group 2A

Vauquelin discovered an element he called gluinium as an oxide in beryl. The name reflected the sweet taste of the oxide. When Friedrich Wölhler and A. Bussy isolated the element in 1828, Wohler renamed it beryllium. Adair Crawford noted the existence of strontium in minerals in 1790.

Physical Properties

Beryllium's strength and rigidity make it an ideal material for mid-range and tweeter diaphragms. In most loud speakers, a current alternating at the frequency of the sound that generated it flows through a coil. As the coil is attracted to and repelled by a permanent magnet, the coil and the cone-shaped diaphragm attached to the coil vibrate. The vibration of the diaphragm reproduces the original sound. A beryllium diaphragm can reproduce frequencies that cannot be heard when other materials are used.

Sources

To Do

Help students write balanced equations and classify the reactions involved in the production of magnesium.

(1) Decomposition

$CaCO_3(s) \xrightarrow{\Delta} CaO(s) + CO_2(g)$

(2) Combination

$CaO(s) + H_2O(l) \rightarrow Ca(OH)_2(aq)$

(3) Double-replacement

$Ca(OH)_2(aq) + MgCl_2(aq) \rightarrow Mg(OH)_2(s) + CaCl_2(aq)$

(4) Double-replacement/neutralization

$Mg(OH)_2(s) + 2HCl(aq) \rightarrow MgCl_2(aq) + 2H_2O(l)$

(5) Decomposition

$MgCl_2(aq) \xrightarrow{elec.} Mg(s) + Cl_2(g)$

(6) Combination

$Cl_2(g) + H_2(g) \rightarrow 2HCl(l)$

Students may wonder what the point is of reactions (3) and (4). The precipitation of $Mg(OH)_2$ is used to concentrate the magnesium. If you add 250 mL of 0.1*M* $Ca(OH)_2$ to 250 mL of seawater, students can observe the precipitate, which can be separated from the remaining solution by decanting or filtration.

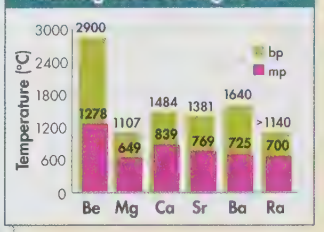
GROUP 2A

Beryllium discovered in 1798 by Nicholas Vauquelin

Magnesium isolated in 1808 by Sir Humphry Davy

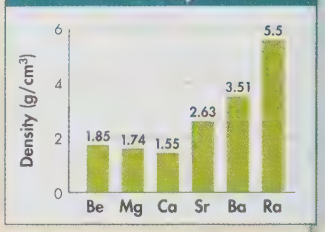
Calcium discovered in 1808 by Sir Humphry Davy

Strontium discovered in 1808 by Sir Humphry Davy



Barium discovered in 1808 by Sir Humphry Davy

Radium discovered in 1898 by Marie Curie & Pierre Curie



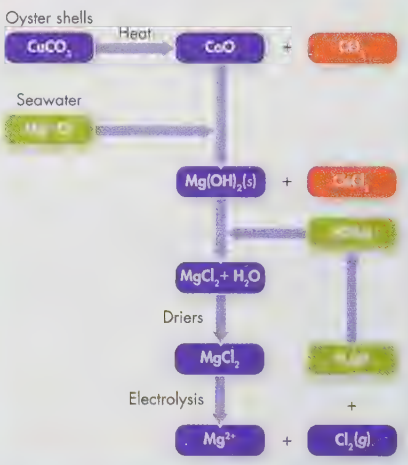
Physical Properties

- Alkaline earth metals are relatively soft, but harder than alkali metals.
- Alkaline earth metals have a gray white luster when freshly cut. When exposed to air, they quickly form a tough, thin oxide coating.
- Densities, melting points, and boiling points tend to be higher than for the alkali metal in the same period.
- Magnesium alloys are strong and lightweight. They are used in cameras, lawnmowers, aircraft, and automobiles.

Melting and Boiling Points

Density

Sources

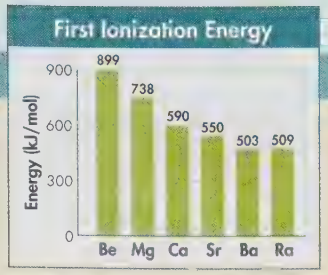


- Alkaline earth metals are not found in nature in the elemental state.
- Many mountain ranges contain alkaline earth carbonates—limestone ($CaCO_3$) and dolomite ($CaCO_3 \cdot MgCO_3$).
- Barium is produced by reducing its oxide with aluminum at high temperature.

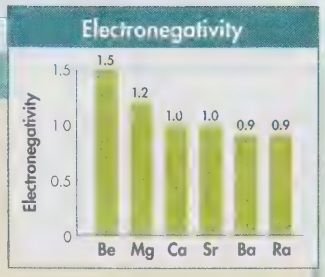
$3BaO(s) + 2Al(s) \longrightarrow 3Ba(l) + Al_2O_3(s)$

- Salts of highly radioactive radium are by-products of uranium refining.

Oyster shells containing $CaCO_3$ are used to extract magnesium from seawater. The chlorine gas produced during the electrolysis of magnesium chloride is fed back into the process.



Production of Magnesium



R6 Elements Handbook

Atomic Properties

- Alkaline earth metals have an electron configuration that ends in ns^2.
- The alkaline earth metals are strong reducing agents, losing 2 electrons and forming ions with a 2+ charge.
- Because radium is luminous, it was once used to make the hands and numbers on watches glow in the dark.
- The ratio of ^{87}Sr to ^{86}Sr varies with location. This data is used to solve puzzles, such as the source of timber used in prehistoric buildings.

	Be	Mg	Ca	Sr	Ba	Ra
Atomic radius (pm)	113	160	197	215	224	223
Ionic radius (pm)	44 Be^{2+}	66 Mg^{2+}	99 Ca^{2+}	112 Sr^{2+}	134 Ba^{2+}	143 Ra^{2+}

Calcium, strontium, and barium can be identified by the colors produced when their compounds are heated in a flame.

Calcium Strontium Barium

Important Compounds and Reactions

- Alkaline earth metals are less reactive than alkali metals.
- Alkaline earth metals react with halogens to form ionic halides. Example:

  $Mg(s) + Br_2(l) \longrightarrow MgBr_2(s)$
- All Group 2A metals (except Be) react with water to form an alkaline solution. Example:

  $Sr(s) + 2H_2O(l) \longrightarrow Sr(OH)_2(aq) + H_2(g)$
- Alkaline earth metals react with oxygen to form binary oxides. Example:

  $2Ca(s) + O_2(g) \longrightarrow 2CaO(s)$

  $\Delta H = -635.1$ kJ/mol
- Heating limestone produces lime, CaO.

  $CaCO_3(s) \xrightarrow{\Delta} CaO(s) + CO_2(g)$

  $\Delta H = 176$ kJ/mol
- Slaked lime, $Ca(OH)_2$, reacts with carbon dioxide to form limestone.

  $Ca(OH)_2(s) + CO_2(g) \longrightarrow CaCO_3(s) + H_2O(g)$
- Barium peroxide is used as a dry powdered bleach. It reacts with water to form the bleaching agent, hydrogen peroxide.

  $BaO_2(s) + 2H_2O(l) \longrightarrow H_2O_2(aq) + Ba(OH)_2(aq)$
- Gypsum, calcium sulfate dihydrate, $CaSO_4 \cdot 2H_2O$, is used to make plasterboard.
- Calcium phosphate, $Ca_3(PO_4)_2$, is the major component of bone and tooth enamel.

Slaked lime is an ingredient in plaster, cement, and the mortar used in this stone wall.

Atomic Properties

One of the puzzles that the ratio of ^{87}Sr to ^{86}Sr was used to solve was the source of timber for the prehistoric great houses in Chaco Canyon, New Mexico. Of the more than 200,000 trees that were used to build the houses, at least one-fifth were spruce or fir trees that were carried from mountainous sites 75–100 km away. Scientists can identify specific sites by comparing $^{87}Sr/^{86}Sr$ ratios in beams to ratios in trees from the sites. The ratios show that the timber for construction beams came from the Chuska and San Mateo mountains, but not from the San Pedro Mountains.

Important Compounds and Reactions

To Do

Students could look at the relationship between solubility and the properties and uses of calcium oxide, calcium carbonate, calcium sulfate, and calcium phosphate. Refer to Table B.7 on page R48.

Group 2A

Mg Chlorophyll

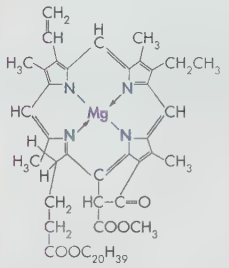
Chlorophyll is an example of a chelate, a substance in which a central metal ion is bonded to a large organic molecule. There are two types of chlorophyll. In chlorophyll *b,* CHO replaces the methyl group at the upper right in the formula. Chlorophyll absorbs light in the red and blue-violet regions of the visible spectrum. In chlorophyll *a* and chlorophyll *b,* the peaks are at different wavelengths. Thus, chlorophyll absorbs a broader range of wavelengths than it would if there were only one type.

Sr Ba Fireworks

The first fireworks were probably invented in China more than a thousand years ago. They were a mixture of sulfur, charcoal, and potassium nitrate, which burned quickly with a flash. This black powder is still a major component of modern fireworks. When iron filings or copper or zinc were added to this gunpowder, early versions of fireworks with limited colors (orange, yellow, white) were produced. The rest of the colors were not added to the palette until the 1800s.

The pattern produced by a shell depends on how the stars are arranged within the shell. Shells are named for their patterns—*chrysanthemum, weeping willow, or strobe.* Strobes are clusters of flickering silvery lights that drift slowly to the ground. The gold sparks in a display come from burning iron filings or charcoal. Brilliant white flames are produced when magnesium, titanium, and aluminum burn at very high temperatures.

To Do



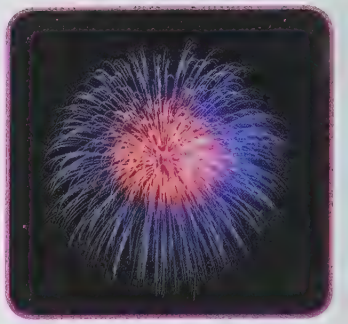
Because fireworks displays are often a central part of public celebrations, students may not realize that fireworks are classified as hazardous materials. Suggest that students investigate the hazards associated with the misuse of fireworks, and the regulations that are in place in your state to prevent injuries.

GROUP 2A

Mg Chlorophyll

A plant that is deprived of magnesium will turn yellow and eventually die. The yellow color is a sign that the plant is not producing enough of the green pigment chlorophyll, which is found in structures called chloroplasts. One square millimeter of a leaf's surface contains about half a million chloroplasts. In chloroplasts, light energy is changed to chemical energy.

Chlorophyll molecules absorb wavelengths of blue light and red light, and reflect green light. There is a magnesium ion at the center of each chlorophyll molecule. It is embedded like a jewel in a crown-like ring. The magnesium ion forms a bond with each nitrogen atom.

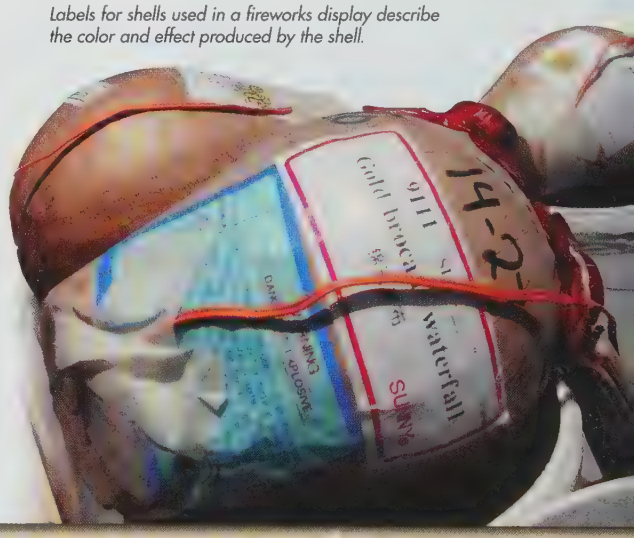


Chlorophyll a

Chlorophyll is typical of a family of compounds called porphyrins, which contain a central metal ion. In heme, the ion is Fe^{2+}. There are four heme molecules in hemoglobin, which transports oxygen in the blood.

Sr Ba Fireworks

Producing an aerial fireworks display requires skill and knowledge of chemistry. Shells are stored in steel pipes anchored in sand. A typical shell contains two charges, one to launch the shell and one to cause the shell to burst. When the lifting charge explodes, the shell is blown out of the pipe and the fuse attached to the bursting charge ignites. The shell travels for a few seconds before it bursts.



The name of this fireworks effect is chrysanthemum.

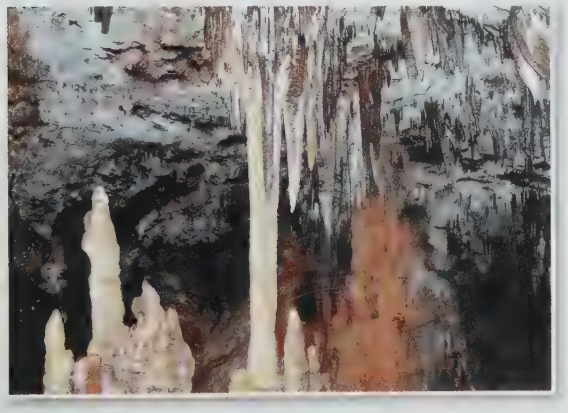
The explosions that launch the shells and cause them to burst are exothermic redox reactions. The reducing agent, or fuel, may be aluminum, magnesium, or sulfur. The oxidizing agent may be a nitrate, a chlorate, or a perchlorate, such as potassium perchlorate ($KClO_4$).

When a shell bursts, it releases tiny pellets called "stars," which produce the colors. Only a few elements are needed to produce these colors. Two are alkaline earth metals, strontium for bright red and barium for light green. These same colors are produced when strontium and barium compounds are heated in a flame. Flame tests can identify elements because an element emits characteristic wavelengths of light when its electrons absorb energy and then return to the ground state.

Labels for shells used in a fireworks display describe the color and effect produced by the shell.

R8 Elements Handbook

Ca Limestone Caves



The chemical reactions that form a limestone cave are simple. Carbon dioxide in the air dissolves in rain to form weak carbonic acid, H_2CO_3. As rain passes through soil, it dissolves carbon dioxide produced by decaying plants and becomes even more acidic. The rainwater seeps into limestone, $CaCO_3$, beneath the soil. The $CaCO_3$ dissolves in the carbonic acid, forming a solution of calcium hydrogen carbonate, $Ca(HCO_3)_2$.

$$CaCO_3(s) + H_2CO_3(aq) \longrightarrow Ca^{2+}(aq) + 2HCO_3^-(aq)$$

Over millions of years, as more and more limestone dissolves, a cave forms and slowly grows in size. Once the cave stops growing, another process may occur. Calcium hydrogen carbonate solution drips through the cave's roof. Carbon dioxide is released from solution, leaving behind a tiny deposit of solid calcium carbonate.

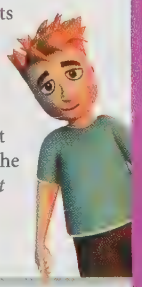
$$Ca^{2+}(aq) + 2HCO_3^-(aq) \longrightarrow CaCO_3(s) + CO_2(g) + H_2O(l)$$

The deposit slowly grows into a stalactite, which hangs from the ceiling like an icicle. Drops of solution that fall from the ceiling form stalagmites on the cave floor. Calcium carbonate is white. So any color in the deposits is due to traces of metal ions, such as copper (blue-green) and iron (red-brown). The growth rate of the formations depends mainly on the volume of water that drips through the roof and the concentration of calcium hydrogen carbonate in the water. In many caves, the rate of growth is measured in centimeters per hundreds or thousands of years.

Stalactites and stalagmites may join together to form columns.

Ca Building Strong Bones

As a young adult, you can have a major effect on the health of your bones later in life. You acquire 90% of the bone tissue in your skeleton before age 18 as females and age 20 as males. Physical activity and the amount of calcium in your diet are factors that affect the buildup of bone mass.



To maintain a constant level of calcium in your blood, your body may release calcium from bone tissue. If enough calcium is lost from bones, they become brittle and tend to break easily. This condition, known as osteoporosis, is most common in older people. However, it can occur in young and middle-aged adults.

The recommended daily intake of calcium from age 9 to age 18 is 1.3 g per day. This is the amount of calcium in a liter of milk. Calcium-fortified foods, such as orange juice, are a good choice for those who cannot digest the lactose in milk.

Vitamin D helps your body absorb calcium. The vitamin D your skin produces when exposed to sunlight is usually not enough to meet your daily requirement. So orange juice is also fortified with vitamin D.

Did You Know?

Calcium oxide (lime) emits a bright white light when it is heated. Before electric lights, theaters could spotlight a single actor by focusing the light from heated lime. Thus, the expression *in the limelight* describes a person in a prominent position.

Ca Limestone Caves

Limestone caves tend to be longer and more complex than other types of caves. Limestone is a sedimentary rock, which generally forms in warm, shallow seas. When the water table drops in a limestone cave, dry spaces that can be explored are left. It is in these dry spaces that stalactites and stalagmites form.

Ca Building Strong Bones

In recent years there has been a debate about how the increased consumption of soft drinks by teens has affected the calcium content of their bones. One hypothesis is that acids in soft drinks interfere with absorption of calcium. Another is that the consumption of soft drinks reduces the consumption of calcium sources such as milk.

Group 3A

Physical Properties

To Do

To celebrate its 80th anniversary, *Chemical & Engineering News* published an issue on the elements (September 8, 2003). Go to their Web site for instructions on accessing the issue online, purchasing multiple copies, and ordering a free issue for yourself via e-mail. Students are likely to enjoy the article on gallium by Oliver Sacks.

Sources

In the Elements Handbook, students will often see references to minerals and ores. A mineral is a naturally occurring, inorganic, crystalline solid with a characteristic chemical composition. Some properties used to identify minerals are crystal structure, color, luster, density, hardness, and how its crystals fracture. An ore is a material from which a valuable mineral can be profitably extracted.

GROUP 3A

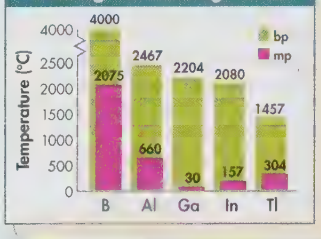
Boron discovered in 1808 by Sir Humphry Davy and by Joseph-Louis Gay-Lussac & Louis-Jacques Thénard

Aluminum discovered in 1825 by Hans Christian Oersted

Gallium discovered in 1875 by Paul-Emile Lecoq de Boisbaudran

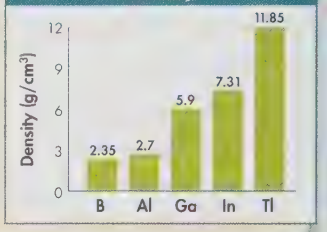
Indium discovered in 1863 by Ferdinand Reich & Hieronymus T. Richter

Thallium discovered in 1861 by Sir William Crookes



Physical Properties

- Boron is a metalloid. The rest of the Group 3A elements are metals.
- Aluminum is a valuable structural material because of its strength, especially in alloys with silicon or iron. These alloys have a low density and resist corrosion.
- Gallium has an extremely wide liquid temperature range (30°C to 2204°C). Solid gallium floats in liquid gallium, which is unusual for a metal.



Boron is black, lustrous, and extremely hard, but brittle.

Melting and Boiling Points

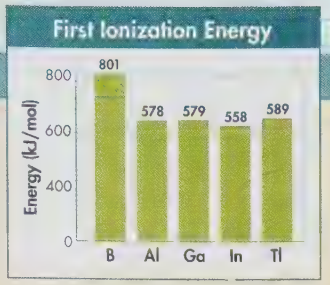
Density

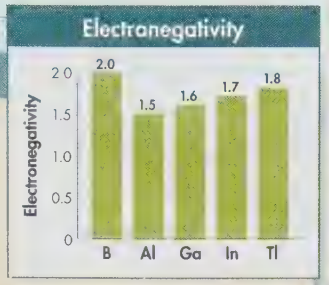
Sources

- Boron is always combined with oxygen in nature. Boron can be prepared by the reaction of its oxide with magnesium metal.

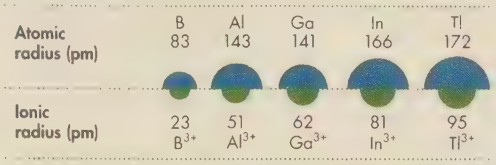
  $B_2O_3(s) + 3Mg(s) \longrightarrow 2B(s) + 3MgO(s)$

- Bauxite is a common ore of aluminum. The primary mineral in bauxite is alumina, Al_2O_3, which is reduced to aluminum by electrolysis.
- Gallium, indium, and thallium are quite rare. They are typically extracted from ores being processed to extract other metals.





The conveyor belt is being used to unload bauxite from a train. Bauxite is a major source of aluminum. It is also a source of gallium.



R10 Elements Handbook

Atomic Properties

- Group 3A elements have an electron configuration that ends in ns^2np^1.
- The most common oxidation number for boron, aluminum, gallium, and indium is +3. For thallium, it is +1.
- Group 3A elements become more metallic from top to bottom within the group.
- Radioactive thallium-201 is injected into patients taking a stress test used in the diagnosis of heart disease.

Important Compounds and Reactions

- Group 3A elements react with halogens to form halides. Example:

  $2Al(s) + 3Cl_2(g) \longrightarrow 2AlCl_3(s)$

  Aluminum chloride is used as a catalyst in organic reactions.
- Group 3A elements react with oxygen to form oxides. Example:

  $4Al(s) + 3O_2(g) \longrightarrow 2Al_2O_3(s)$

  $\Delta H = -1676$ kJ/mol

  Because this reaction is so exothermic, powdered aluminum is a component of some explosives, fireworks, and rocket fuels.
- Aluminum sulfate (alum), $Al_2(SO_4)_3 \cdot 18H_2O$, is used as a coagulant in water treatment plants.
- Gallium arsenide, GaAs, converts electric current to light in light-emitting diodes (LEDs). It is produced as follows.

  $(CH_3)_3Ga(g) + AsH_3(g) \longrightarrow GaAs(s) + 3CH_4(g)$

This LED is shown at about five times actual size.

Corundum is a mineral form of aluminum oxide. Rubies are corundum in which a few aluminum ions have been replaced by chromium ions.

- Borax, $Na_2B_4O_7 \cdot 10H_2O$, is used to soften water and is found in glasses and glazes. When a mixture of borax and hydrochloric acid is heated, boric acid is produced.

  $Na_2B_4O_7(aq) + 2HCl(aq) + 5H_2O(l) \longrightarrow 4H_3BO_3(aq) + 2NaCl(aq)$
- Boric acid is poisonous if ingested. The solid is used as an insecticide against cockroaches. A dilute solution of boric acid is an eyewash.
- Boron carbide, B_4C, is almost as hard as diamond. It is used for items that must resist wear, such as cutting tools.
- Laboratory glassware is made of heat-resistant glass containing 12% to 15% boric oxide.

Atomic Properties

To Do

Challenge students to figure out why thallium commonly has an oxidation number of +1 in addition to +3 when other elements in the group do not. Thallium can lose an electron from a 6*p* orbital more easily than the other elements can lose an electron from their highest occupied *p* orbital because the energy difference between the 6*s* and 6*p* orbitals is greater than the difference between the *s* and *p* orbitals in the lower principal energy levels. The occupied 4*f* sublevel in thallium is responsible for the difference.

Important Compounds and Reactions

The compositions of sapphires and rubies are almost identical. They are mainly crystals of colorless aluminum oxide (Al_2O_3). Traces of cobalt make sapphires blue and traces of chromium make rubies red.

Crystalline boron nitride is an industrial abrasive, which is used to cut and polish metals. But when finely ground boron nitride is added to face powder, it provides a soft, silky texture.

Group 3A

In Uses of Indium

Traditionally, solder was an alloy of tin and lead, which melts at about 180°C. Nowadays many solders are lead-free and some low-temperature solders do not even contain any tin. One mixture used to solder glass and ceramics is 97% indium and 3% silver. Often a flux is used when metals are being soldered. A flux is used to remove oxides from the surface of metals before they are joined.

To Do

You might want to arrange for a demonstration of soldering by a teacher in your school or another expert. Ask the person doing the demonstration to discuss how the composition of solder affects its properties and its uses.

Al Recycling Aluminum

When old bridges are repaired, the steel or concrete decks may be replaced with aluminum decks. The aluminum decks require much less maintenance because a thin oxide layer protects the underlying layers of aluminum. The aluminum decks can carry equal or greater loads than steel decks because aluminum has a high strength to weight ratio.

Strength is defined as the ability of a material to withstand forces of compression, tension, and shear. At the limit of its compressive strength, a material will tend to compact, i.e., its volume will be reduced. At the limit of its tensile strength, a material will be stretched to the point where it breaks. At the limit of its shear strength, a material will slide along a plane parallel to the force. With a deck on a bridge, the major concern is compressive strength.

GROUP 3A

In Uses of Indium

Indium is a soft metal with a low melting point of 157°C. One useful property of liquid indium is its ability to "wet" glass. It spreads out and forms a thin layer on the glass instead of beading up. This property allows indium to be deposited on glass to make mirrors that are as reflective, but more corrosion-resistant, than silvered mirrors.

Low-melting alloys that contain indium are used as solders to join glass to glass. They also can join a metal to a metal at low temperatures. There are products, such as electronics components, that could be damaged if joined at a high temperature. The seals of some fire sprinkler heads are held in place by indium alloys. When heat from a fire melts the alloy, the seal is released, which allows water to pour from the sprinkler head.

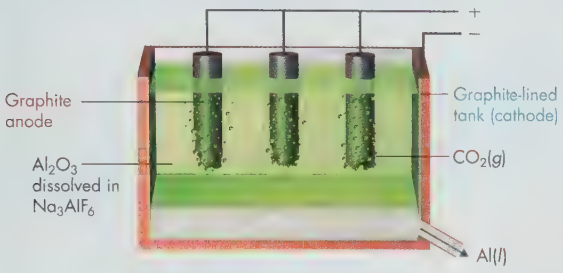
Al Recycling Aluminum

Aluminum is used in durable consumer goods such as baseball bats.

Lightweight, durable aluminum has many uses. When aluminum parts replace steel parts in vehicles, less fuel is needed to travel the same distance. About 20% of the aluminum produced is used for packaging, including foil and cans.

In the United States, over 80 billion aluminum soft drink cans are sold each year. More than 50% of these cans are recycled. The energy saved by recycling just one of these cans could be used to operate a television for three hours. The energy needed to recycle aluminum is 5% of the energy needed to obtain new aluminum from ore. An added benefit of recycling is a reduction in solid waste.

Recycled aluminum cans are shredded, crushed, and heated to remove materials other than aluminum. Aluminum pieces about the size of a potato chip are placed in furnaces where they are mixed with new aluminum and melted. Then, the molten aluminum is poured into 7.6-m ingots that have a mass of about 13,600 kg. The ingots pass through rolling mills that reduce their thickness from about 0.5 m to about 0.25 mm. The thin sheets are coiled and shipped to a manufacturer who produces the bodies and tops of the cans. Aluminum from a recycled can is part of a new can within 60 days.



Aluminum cans are compressed before being shipped to aluminum companies for recycling.

Al Manufacturing Aluminum

Aluminum is the most abundant metal in Earth's crust (8.3% by mass). It is found in minerals such as bauxite (impure aluminum oxide, Al_2O_3). But for years after its discovery, there wasn't a practical way to extract aluminum from its ores. This rare and expensive metal was used, like gold, mainly for decoration.

A professor at Oberlin College in Ohio challenged his class to find an inexpensive way to produce aluminum. In 1885, Charles Hall responded to the challenge. He set up a laboratory in a woodshed. He knew that other chemists had tried to decompose aluminum oxide by electrolysis. This method was not practical because the melting point of aluminum oxide is quite high (2045°C). Hall found that mixing aluminum oxide with cryolite (Na_3AlF_6) produced a mixture that melted at a much lower temperature of 1012°C.

The process Hall invented is often called the Hall-Heroult process. Paul Heroult, a 23-year-old Frenchman, developed the same process almost simultaneously. It is still used today. Pure aluminum oxide is extracted from bauxite through heating to a temperature above 1000°C. The aluminum oxide is dissolved in molten cryolite and contained in a graphite-lined iron tank. The graphite rods used as an anode are consumed during the process.

$$\text{Anode: } C(s) + 2O^{2-}(l) \longrightarrow CO_2(g) + 4e^-$$

$$\text{Cathode: } 3e^- + Al^{3+}(l) \longrightarrow Al(l)$$

The products are carbon dioxide and molten aluminum metal. Because the aluminum is more dense than the aluminum oxide-cryolite mixture, it collects at the bottom of the tank and is drawn off periodically.

Al Anodized Aluminum

If an aluminum object, such as a flashlight, has a color other than silver, it was anodized before it was dyed. The main goal of anodizing is to protect the aluminum from corrosion by coating it with aluminum oxide. The ability to be dyed is an added benefit.

The aluminum object becomes the anode in an electrolytic cell. The electrolyte is a dilute acid. When an electric current flows through the cell, aluminum oxide forms on the surface of the aluminum.

The oxide layer is thin, hard, and dense. It contains tiny pores, which can absorb an organic dye. If a dyed piece is placed in boiling water, the oxide layer absorbs water and swells. The swelling closes the pores and seals in the dye. Because the oxide layer is so thin, the silver of the aluminum base is visible through the dye and gives the object a metallic sheen.

Did You Know?

Indium's name comes from indigo, a bright line in its emission spectrum. Indium will emit a high-pitched sound when it is bent. Tin and gallium also "cry" when bent.

Al Manufacturing Aluminum

Hall was able to convince a group in Pittsburgh to invest in his process. The investors formed the Pittsburgh Reduction Company, which became the largest producer of aluminum in the United States. The company was later renamed the Aluminum Company of American (Alcoa). Hall bequeathed much of the fortune he made to various universities. Oberlin College received three million dollars in 1914, which is equivalent to more than 50 million dollars today.

Al Anodized Aluminum

Untreated elemental aluminum cannot absorb enough dye, even if the metal is immersed in a coloring bath, to color the aluminum.

To Do

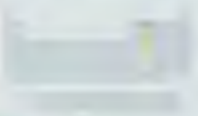
If you or one of your students has access to an aluminum object that has been anodized, bring the object to class for other students to observe.

Group 4A

See Roald Hoffmann's article on silicon from the 80th anniversary issue of *Chemical & Engineering News* for an explanation for why silicon plays so minor a role in biological processes in comparison to carbon.

Physical Properties

Based on their macroscopic properties, it isn't obvious that diamond and graphite have the same chemical composition. In 1772, Lavoisier demonstrated that diamond was carbon by analyzing the products produced when equal masses of diamond and charcoal were burned.



Sources

The orthosilicate ion, SiO_4^{4-}, is found in minerals such as zircon, $ZrSiO_4$. Several minerals contain the disilicate ion, $Si_2O_7^{6-}$, in which an oxygen atom is shared by two silicon atoms. In most silicates, the tetrahedra are linked together in chains or sheets, as in talc, $Mg_3(Si_2O_5)_2(OH)_2$. The repeating unit in a chain is $Si_2O_6^{4-}$, or SiO_3^{2-}. The repeating unit in a sheet is $Si_2O_5^{2-}$. Silicates that contain more than one metal can have a variable composition as long as the total charge on the cations is constant.

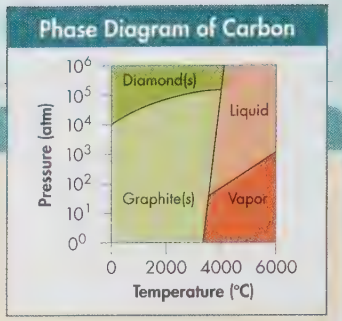
To Do

Andalusite belongs to a subclass of silicates called nesosilicates. Pyrophyllite belongs to the subclass phyllosilicates. Students could research the six subclasses of silicates and explain the basis of the classification system. The subclasses are nesosilicates (single unit), sorosilicates (double unit), inosilicates (single and double chains), cyclosilicates (rings), phyllosilicates (sheets), and tectosilicates (frameworks).

GROUP 4A

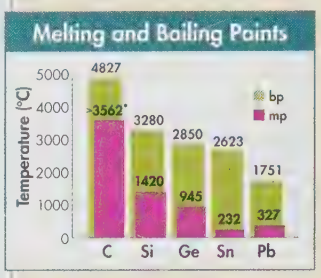
Carbon known since ancient times

Silicon discovered in 1824 by Jöns Jacob Berzelius



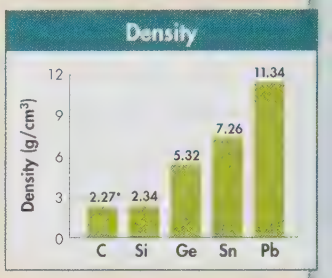
Germanium discovered in 1886 by Clemens Winkler

Tin known since ancient times



Lead known since ancient times

Physical Properties



- Group 4A elements are all solids at room temperature.
- The metallic properties of Group 4A elements increase from carbon to lead.
- Diamond, graphite, and buckminsterfullerene are three allotropes of carbon.

Graphite is more stable than diamond at STP, but the activation energy is too high for diamond to change to graphite at these conditions.

*diamond

*graphite

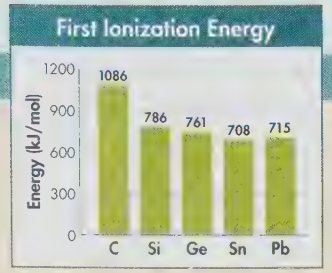
Sources

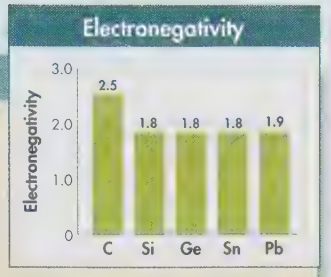
- Carbon is found in nature as an element, in Earth's atmosphere as carbon dioxide, in Earth's crust as carbonate minerals, and in organic compounds produced in cells.
- Silicon can be produced by the reduction of silicon dioxide (silica) with magnesium, carbon, or aluminum. Example:

  $SiO_2(s) + 2Mg(s) \longrightarrow Si(s) + 2MgO(s)$
- Tin is prepared by reduction of the mineral cassiterite, SnO_2.

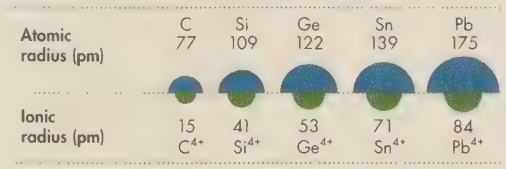
  $SnO_2(s) + 2C(s) \longrightarrow 2CO(g) + Sn(s)$
- Lead is refined from the mineral galena, PbS. Galena is heated in air to form a mixture of PbO and $PbSO_4$. Lead is produced through further reaction of these compounds with PbS.

Al_2SiO_5
andalusite

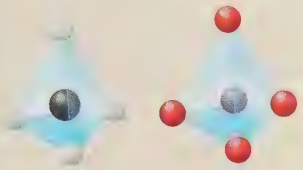




$AlSi_2O_5OH$
pyrophyllite



About 90% of the minerals in Earth's crust are silica and silicates. In silicates, each silicon atom is surrounded by three or four oxygen atoms. These units can be linked together in chains, sheets, rings, or crystals.



Atomic Properties

- Group 4A elements have an electron configuration that ends in ns^2np^2.
- For Group 4A elements, the most common oxidation numbers are +4 and +2. For carbon, −4 is also common.
- Silicon and germanium are semiconductors.

CH_4
methane molecule

SiO_4^{4-}
silicate ion

When carbon and silicon form four covalent bonds, there is often sp^3 hybridization. The result is compounds and ions with tetrahedral structures.

Important Compounds and Reactions

- Group 4A elements are oxidized by halogens.
  $Ge(s) + 2Cl_2(g) \longrightarrow GeCl_4(l)$
- Group 4A elements combine with oxygen to form oxides. Example:
  $Sn(s) + O_2(g) \longrightarrow SnO_2(s)$
- Complete combustion of hydrocarbons yields carbon dioxide and water. Example:
  $CH_4(g) + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(l)$
  $\Delta H = -890$ kJ/mol
- Plants use carbon dioxide to produce carbohydrates and oxygen.
- Aqueous sodium silicate, Na_2SiO_3, is used as an adhesive for paper, as a binder in cement, and to stabilize shale during oil drilling.
  $SiO_2(s) + 2NaOH(aq) \longrightarrow Na_2SiO_3(aq) + H_2O(l)$
- Acetylene is a fuel used for welding. It forms when calcium carbide and water react.
  $CaC_2(s) + 2H_2O(l) \longrightarrow C_2H_2(g) + Ca(OH)_2(aq)$
- Tungsten carbide, WC, is used on the cutting surfaces of drill bits and saw blades.
- Tin(II) fluoride, SnF_2, is used in some toothpastes to prevent tooth decay.

Silicon dioxide, SiO_2, is the sand on many beaches. It is used to make glass, including glass that is "stained" with metallic salts. The pieces of glass in this window are held together with strips of lead.

Atomic Properties

The graphs for first ionization energy and electronegativity can help you discuss the fact that the first element in a group of representative elements is often the least representative of the group as a whole. The elements in period 2 have only the electrons in the 1*s* orbital to shield the valence electrons from the attraction of the nucleus.

Important Compounds and Reactions

A mixture of sand (SiO_2), lime (CaO), and soda ash (Na_2CO_3) is used to make glass. The addition of small amounts of transition metal oxides can change the color of glass. Adding iron(III) oxide (Fe_2O_3) gives glass the green tint used in some beverage bottles and tinted windows. Blue glass contains CuO or CoO, orange glass contains Cr_2O_3, and red glass contains colloidal gold.

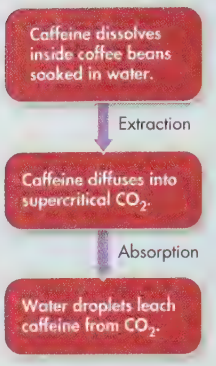
Group 4A

C Green Chemistry

The phrase "green chemistry" was coined in 1992 to define an approach to developing chemical technology. The green chemistry mission statement of the EPA is "to promote innovative chemical technologies that reduce or eliminate the use or generation of hazardous substances in the design, manufacture, and use of chemical products." The EPA program supports research and education through partnerships with industries, academia, other government agencies, and non-government agencies. Los Alamos National Laboratory is one important partner. Los Alamos was instrumental in the development of supercritical carbon dioxide as a recyclable cleaning solvent. Los Alamos has collaborated with industries on projects ranging from fuel cells to a process for producing ethylene that will reduce carbon dioxide emissions and conserve natural gas.

Caffeine is an alkaloid. The amount of caffeine in a coffee bean is typically 1% to 2% by mass. Around 1900, a German chemist, Ludwig Roselius, became interested in extracting caffeine from coffee because he blamed his father's death on the drinking of excessive amounts of coffee. There were a number of solvents that could remove the caffeine from coffee, but most were known to be toxic. By the 1980s, the solvent used for 70 years, methylene chloride, was suspected to be a carcinogen. Ethyl acetate and water are also used to decaffeinate coffee.

GROUP 4A



C Green Chemistry

The term *green chemistry* was coined in 1992. It describes the effort to design chemical processes that don't use or produce hazardous substances. The goal is to protect the environment and conserve resources. For example, if a catalyst is used to reduce the temperature at which a reaction occurs, the process requires less energy.

Carbon dioxide is at the center of a green chemistry success story. Organic solvents are used to dissolve substances that are insoluble in water. Many of these solvents are toxic. It can be difficult to remove all traces of the toxic solvent from reaction products and safely recycle or dispose of the solvent. Supercritical carbon dioxide can replace some organic solvents.

A gas becomes a supercritical fluid at a temperature and pressure called its critical point. For carbon dioxide, this occurs at 31.1°C and about 100 atmospheres. At its critical point, carbon dioxide is in a hybrid state. It has a high density (like a liquid) but it is easily compressed (like a gas). Many organic compounds dissolve in supercritical carbon dioxide. The solvent is easily separated from a reaction mixture because it evaporates at room temperature and atmospheric pressure. It is also used to separate substances from mixtures. It can extract caffeine from coffee beans, dry-clean clothes, or clean circuit boards.

Decaffeinating Coffee

After the caffeine is extracted, the coffee beans are dried and roasted. The aqueous solution of caffeine is sold to soft drink manufacturers.

Si Optical Glass

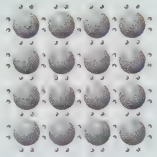
Glass is a material with the structure of a liquid, but the hardness of a solid. In most solids, the particles are arranged in an orderly lattice. In solid glass, the molecules remain disordered, as in a liquid. The main ingredient in most glass is silica (SiO_2), which is one of the few substances that can cool without crystallizing.

The glass used in eyeglasses, microscopes, and telescopes is called optical glass. This type of glass is purer than window glass and transmits more light. Optical glass can be drawn into long fibers that are used like tiny periscopes to view tissues deep within the human body.

In an optical fiber, light travels through a thin glass center called the core. A second glass layer reflects light back into the core. An outer plastic layer protects the fiber from damage. The transmission of light signals through glass is called fiber optics.

When the fibers are bundled into cables, they often replace electrical cables in computer networks. They are also used to transmit television signals and phone calls over long distances.

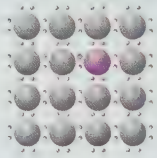
Si Optical Glass



A light signal can travel a great distance through the core of an optical fiber because the cladding doesn't absorb any light. Impurities in the cladding cause the signal to degrade, which is why the glass must be optical glass. Optical fibers are cheaper than copper wires of equivalent length. Because an optical fiber can have a smaller diameter than a copper wire, more fibers can be bundled into a cable with the same diameter.

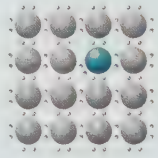
To Do

Students may want to research what is happening in eyeglass lenses that darken when exposed to light. When lenses containing silver chloride are exposed to bright light, the silver chloride breaks down, releasing opaque silver atoms. These atoms reduce the amount of light that can penetrate the lens. When the amount of available light is reduced, the silver and chlorine atoms re-associate and the glass becomes clear again.



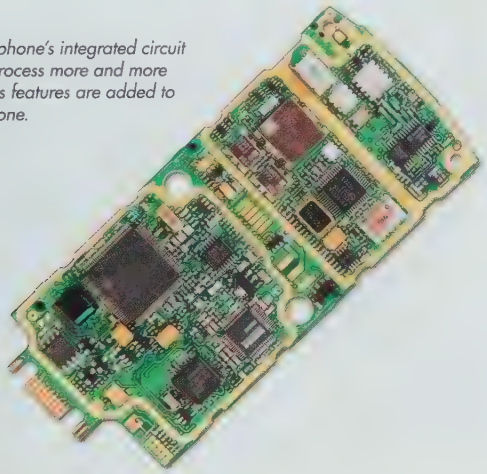
Si Semiconductors

With a cellular phone, you can call or text your friends from almost any location. Most phones also let you read and send e-mails, get directions, take a photograph, listen to music, or access the latest news. How can such a complex device be small enough to fit in your pocket? Semiconductor technology is responsible.



Pure silicon

Silicon is a semiconductor. In its pure form, it conducts an electric current better than most nonmetals but not as well as metals. But its ability to conduct can be changed dramatically by doping, or adding traces of other elements, to the silicon crystal.

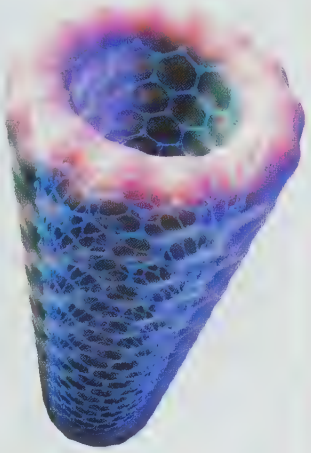


n-type (with arsenic)

Doping with arsenic produces a donor, or n-type, semiconductor. Each arsenic atom has five valence electrons, compared with four for silicon. So there are extra electrons in the crystal. Doping with boron produces an acceptor, or p-type, semiconductor. Because boron has only three valence electrons, there is a positive "hole" in the crystal for every boron atom. The extra electrons or holes are free to move and conduct an electric current.

p-type (with boron)

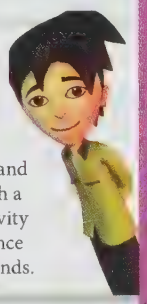
Combinations of n-type and p-type semiconductors are used to build tiny electronic components. An integrated circuit containing millions of components can fit on a small semiconductor wafer. The resulting "chip" can be used to control devices such as computers, calculators, DVD players, televisions, and phones.



A cell phone's integrated circuit must process more and more data as features are added to the phone.

C Beyond Buckyballs

Buckminsterfullerene (C_{60}) is one member of a family of fullerenes. These structures are closed-cage spherical or nearly spherical forms of elemental carbon. The cages are networks of 20 to 600 carbon atoms.



Scientists have verified the existence of nesting spheres of fullerenes. C_{60} can be nested inside C_{240}, and this pair can be nested inside C_{543}. These nesting structures are sometimes called bucky-onions because they resemble the layers of an onion.

Dr. Sumio Iijima discovered a tubular fullerene, or carbon nanotube, in Japan in 1991.

Did You Know?

One name for diamonds is "ice." A diamond can quickly draw heat from your hand when you touch it. Such a high thermal conductivity is unusual for a substance containing covalent bonds.

Si Semiconductors

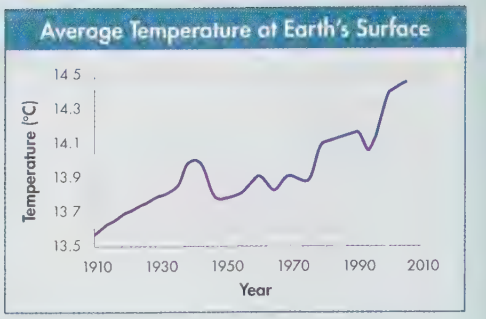
The essential components of a cell phone are a circuit board, antenna, liquid crystal display, keyboard, microphone, speaker, and battery. On the circuit board are analog-to-digital and digital-to-analog chips to translate the outgoing and incoming signals. There is a system processor that performs millions of calculations per second for the manipulation of the signals and a microprocessor that handles the keyboard, display, and all other functions.

C Beyond Buckyballs

The intensive properties of a material are degraded by structural defects. For example, if there is a tiny crack in a steel wire, the strength of the wire will be significantly reduced. Because tubular fullerenes are molecules, they don't have the structural defects associated with multi-wall carbon fibers. With molecules, it is also possible to reliably predict chemical changes.

Group 4A

C Greenhouse Gases



The Intergovernmental Panel on Climate Change (IPCC) was founded in 1988 to review the evidence and assess the impact of climate change. The IPCC published major reports in 1990, 1995, 2001, and 2007. The fifth report is planned for 2013 or 2014. (See the IPCC Web site for a statement on IPCC principles and procedures.) The IPCC has concluded that Earth's temperature increased by 0.6°C since the late 1880s and is likely to increase by another 1.9–2.9°C by 2100.

The source for the data in the graph is the Goddard Institute for Space Studies. The 10 warmest years in the 1900s occurred in the last 15 years of the century. 1998 was the warmest year since scientists began recording global mean surface temperatures. During the 1900s, sea level rose 4–8 inches, and there was a decrease in both snow cover in the Northern Hemisphere and floating ice in the Arctic Ocean. Precipitation over land increased worldwide by about 1%.

Carbon dioxide is not the only greenhouse gas. Methane (CH_4), nitrous oxide (N_2O), sulfur hexafluoride (SF_6), and chlorofluorocarbons (CFCs) exist in much smaller quantities but produce a more powerful greenhouse effect than CO_2. For example, PFCs have a global warming potential of up to 7000 times that of CO_2. The atmospheric content of these gases is also rising as a result of human activities.

C Greenhouse Gases

There are gases in Earth's atmosphere that are called greenhouse gases because they act like the glass in a greenhouse. Sunlight easily passes through these gases to Earth's surface. Some of the solar energy is reflected off the surface as infrared radiation. This radiation is absorbed by greenhouse gases and radiated back to Earth. By trapping infrared radiation, the greenhouse gases keep Earth's surface about 33°C warmer than it would be otherwise.

With an increase in greenhouse gases, more infrared radiation is trapped, causing global warming.

The glass in a greenhouse traps infrared radiation.

Carbon dioxide (CO_2) is the most abundant greenhouse gas. It is released into the air as a product of cellular respiration and removed from the air during photosynthesis. Such interactions normally keep the amount of atmospheric CO_2 in check. But the burning of fossil fuels releases more than 20 billion metric tons of CO_2 every year. Also, as forests are cleared for agriculture, the ability of plants to remove CO_2 from the atmosphere is reduced.

Scientists agree that a rise of only a few degrees in Earth's temperature could cause problems. They disagree on how severe the problems could be. Could climates change so that farmlands become deserts? Could the melting of ice caps cause sea levels to rise until coastal cities are under water?

Si Composite Materials

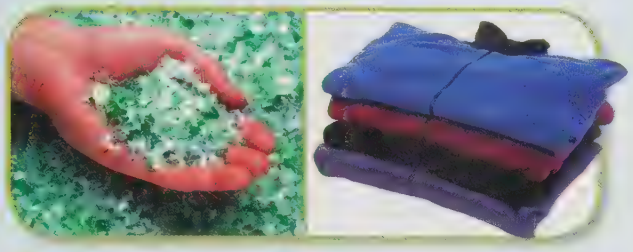
Most composites contain two distinctly different materials. The materials can be arranged in layers as when a sheet of plastic is sealed between panes of glass. Or a composite may consist of a matrix in which fibers of a second material are embedded. Often, the matrix is plastic. The fibers can be carbon.

Composites reinforced with carbon fibers are stronger than steel, yet light in weight. These composites are used in sports equipment, such as hockey sticks and golf clubs. It is less tiring to swing a tennis racket made from a carbon-fiber composite than one made from wood or metal. Carbon-fiber baseball bats act more like wood bats than do aluminum bats.

New aircraft often rely on composite materials. As part of the design process, a model of the plane is placed in a wind tunnel to test what will happen to the aircraft during flight.

Si Composite Materials

Composites are heterogeneous mixtures. Most composites consist of a binder, or matrix, and a reinforcement, which is stronger and stiffer than the matrix. The matrix holds the reinforcement, which can be in the form of particles or fibers, together. In concrete, cement is the matrix and gravel the reinforcement.



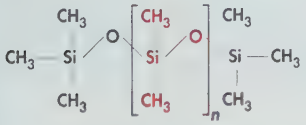
To Do

Students who play a string instrument may want to research and report on the properties of bows made from carbon-fiber composites. (If students research composites they are likely to see the terms *carbon fiber* and *graphite fiber* used interchangeably. They are also likely to see *bonded* used to describe how the reinforcement is held in a matrix.)

C Recycling Plastics

At about 2 kg of waste per person per day, the United States leads the world in the production of solid waste. Luckily, the United States is also a leader in recycling. It is important to recycle plastics because they are made from crude oil, a non-renewable resource. Also, some plastics release toxic gases, such as hydrogen cyanide (HCN) and hydrogen chloride (HCl), when they burn in an incinerator. Finally, plastics are used for packaging material because they do not decay when exposed to sunlight, water, or microorganisms. The downside of this resistance to decay is that plastics can remain unchanged in dumps and landfills for decades.

Plastics are usually sorted by type before they are melted and reprocessed. The plastics industry has a code to identify types of plastics. The numeral 1 is assigned to polyethylene terephthalate (PET), which is used in soft-drink bottles. The numeral 2 refers to high-density polyethylene (HDPE), which is used in milk jugs and shampoo bottles. These are the two types in greatest demand. Carpets and clothing are made from recycled PET fibers. Recycled HDPE is used as a wood substitute for decks and benches.



Fleece clothing often contains post-consumer recycled (PCR) plastic.

Si Silicone Polymers

If you have worn hard contact lenses or used shaving cream, you have used a silicone. Silicone polymers have chains in which silicon and oxygen alternate. The properties of silicones depend on the groups that are bonded to the silicon atoms and the length of the chains.

In silicone rubber and resins, there are cross-links between the chains. These silicones repel water and remain elastic, even at low temperatures. They are used in space suits, as gaskets in airplane windows, and as sealants that are squeezed into place and left to harden.

Polydimethylsiloxane

In polydimethylsiloxane, two methyl groups are bonded to each silicon atom in the chain. Polydimethylsiloxane is used as a lubricant in skin and suntan lotions.

C Carbon Monoxide

It is hard to detect colorless, odorless carbon monoxide gas. When it is inhaled, its molecules bind to the hemoglobin in red blood cells. They bind about 200 times more effectively than oxygen molecules do. So less oxygen reaches body tissues. Headaches, dizziness, nausea, and drowsiness are symptoms of low-level carbon monoxide poisoning. Higher levels of carbon monoxide are fatal.

The incomplete combustion of fuel in gas furnaces and space heaters produces carbon monoxide. It also forms, to some degree, in all internal combustion engines. In the United States, cars have catalytic converters, which convert carbon monoxide to carbon dioxide. In most communities, home owners are required to install devices that monitor the carbon monoxide concentration.

Cigarette smoke contains carbon monoxide. The carbon monoxide from one cigarette can remain in a smoker's blood for several hours. Smoking increases the risk of heart attacks because the heart must pump harder to deliver oxygen to cells when the level of oxygen in the blood is reduced.

Did You Know?

Members of the Scott expedition to the South Pole in 1912 may have died because of **tin.** Their supply of paraffin fuel leaked out through tiny holes in the tin-soldered joints of the storage cans because tin slowly changes to a powder below 13°C.

C Recycling Plastics

The numeral 3 is used for polyvinyl chloride, the numeral 4 for low-density polyethylene (LDPE), the numeral 5 for polypropylene, the numeral 6 for polystyrene, and the numeral 7 for all other plastics.

According to the EPA, Americans generated 250 million tons of trash in 2008. About 61 million tons were recovered through recycling and another 22.1 million tons through composting. About 32 million tons were burned with energy recovery. The remaining 54.2% was discarded. Visit the EPA Web site for more data on trends in municipal solid waste in 2008 and in subsequent years.

To Do

Students could research recycling programs in your community. They could find out which items are recycled and where these items are collected (curbside or at designated drop-off sites).

C Carbon Monoxide

The Consumer Product Safety Commission recommends that households install a CO_2 detector with an audible alarm near bedrooms and a second monitor near the heating source.

To Do

Students might want to research the relationship between the level of carbon monoxide in the air near highways and emissions from vehicles. In urban areas, the concentration tends to peak during morning and afternoon rush hours. Carbon monoxide tends to accumulate more in cold weather when engines run less efficiently. Other factors to consider are the presence or absence of wind to disperse pollutants or the presence of inversion layers in the atmosphere.

Si Silicone Polymers

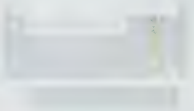
Students will also be familiar with some properties of silicone polymers if they have bounced a superball, stretched Silly Putty, removed a peel off label, placed weather-stripping caulk around a door frame, polished a car, or ingested a remedy for an upset gaseous stomach.

Group 5A

Physical Properties

Cryogen comes from the Greek *kryos,* meaning "icy cold." Foods can be packed, sealed, and sprayed with liquid nitrogen, which absorbs heat as it evaporates. Rapid freezing is also used to preserve tissue samples, such as blood and bone marrow. Surgeons use liquid nitrogen to remove warts and skin cancers.

Sources



Roasting involves heating an ore to a high temperature in a furnace, which causes a reaction of the ore with a gaseous component of the atmosphere in the furnace. The oxidation of sulfide ores is an example of roasting. The products of roasting will be a metal oxide and sulfur dioxide or the elemental metal and sulfur dioxide (depending on the activity of the metal). Roasting of antimony produces the oxide, which can then be reduced with carbon. A flux of sodium sulfate is used to prevent evaporation of molten antimony.

$2Sb_2S_3 + 9O_2 \rightarrow 2Sb_2O_3 + 6SO_2$

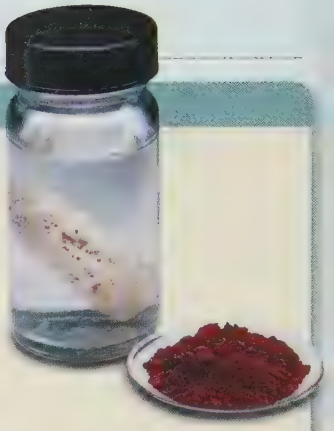
$2Sb_2O_3 + 3C \rightarrow 4Sb + 3CO_2$

GROUP 5A

GROUP 5A

Nitrogen discovered in 1772 by Daniel Rutherford

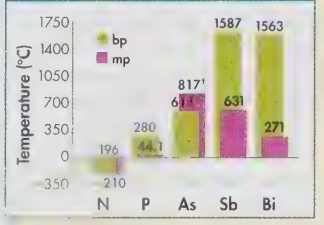
Phosphorus discovered in 1669 by Hennig Brand



Arsenic discovered in 1250 by Albertus Magnus

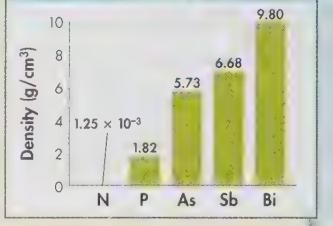
Antimony discovered in 1600s or earlier

Bismuth described in 1450 by Basil Valentine; shown to be a distinct element in 1753 by Claude-François Geoffroy



Physical Properties

- Except for nitrogen gas, Group 5A elements are solid at room temperature.
- The metallic properties of Group 5A elements increase from top to bottom within the group. N and P are nonmetals. As and Sb are metalloids. Bi is a metal.
- Liquid nitrogen is a cryogen, a liquid refrigerant that boils below −190°C.
- Phosphorus has 10 allotropes including white and red.

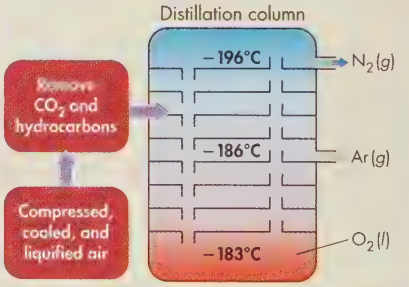


White phosphorus is very reactive and must be stored under water. Red phosphorus is much more stable.

Melting and Boiling Points

Density

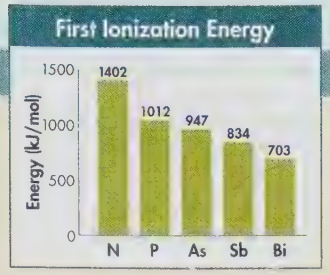
*sublimes † at 28 atm



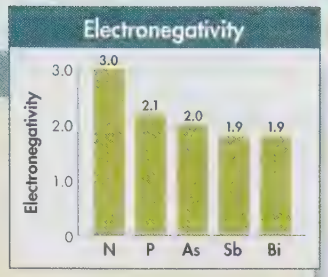
Sources

- Nitrogen is obtained from the fractional distillation of liquefied air.
- Phosphorus is derived from phosphate minerals. Example:

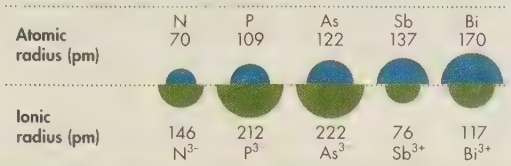
$$Ca_3(PO_4)_2(s) + 3SiO_2(s) + 5C(s) \longrightarrow 2P(l) + 3CaSiO_3(s) + 5CO(g)$$



- Arsenic is prepared by heating a mixture of $FeAs_2$ and FeS_2 in the absence of air.
- Antimony is prepared by roasting the ore stibnite, Sb_2S_3.



Fractional Distillation of Air



Atomic Properties

- Group 5A elements have an electron configuration that ends in ns^2np^3.
- The most common oxidation numbers for Group 5A elements are +3, +5, and −3.
- Nitrogen has oxidation numbers from −3 to +5 (and all numbers in between) in a variety of stable compounds.
- Elemental nitrogen, N_2, is highly unreactive due to its strong N-to-N triple bond.

Important Compounds and Reactions

- Nitrous oxide, N_2O, (laughing gas) is an anesthetic. It is made from ammonium nitrate.

  $NH_4NO_3(s) \xrightarrow{\Delta} N_2O(g) + 2H_2O(g)$

- Nitrogen dioxide, NO_2, is an air pollutant produced when fossil fuels burn at high temperatures.
- Lightning causes the nitrogen and oxygen in air to react and form nitric oxide, NO.
- Poisonous hydrazine, N_2H_4, is used as a rocket fuel. It is prepared by the following reaction.

  $2NH_3(aq) + OCl^-(aq) \longrightarrow N_2H_4(aq) + Cl^-(aq) + H_2O(l)$

  The reaction is complex. One intermediate is chloramine, NH_2Cl, which is also poisonous. The labels on bottles of household ammonia and chlorine bleach warn you not to mix these solutions. If you ignore the warning, chloramine will be produced.
- Nitric acid, HNO_3, is used to make fertilizers and explosives. It is produced by the Ostwald process.
- Phosphoric acid is used in soft drinks and fertilizers. It is made by a double-replacement reaction.

  $Ca_3(PO_4)_2(s) + 3H_2SO_4(aq) \longrightarrow 3CaSO_4(aq) + 2H_3PO_4(aq)$

  Dentists use phosphoric acid to etch the exposed dentine layer of a drilled tooth to help a filling adhere to the tooth.
- Ammonia is synthesized directly from its elements by the Haber-Bosch process.

  $3H_2(g) + N_2(g) \longrightarrow 2NH_3(g)$
- Amino acids such as glycine, H_2NCH_2COOH, are the building blocks of proteins.
- Bismuth subsalicylate, $BiO(C_7H_5O_3)$, is the active ingredient of a pink liquid antacid.
- Arsenic trioxide, As_2O_3, is powerful poison. Its use as a weed killer and insecticide has been restricted.
- Antimony is added to alloys to increase their hardness.

Ostwald Process

Ammonia is oxidized to nitrogen dioxide in two stages. The nitrogen dioxide forms nitric acid as it passes through warm water.

Atomic Properties

The table compares the bond lengths and bond dissociation energies for single, double, and triple nitrogen-nitrogen bonds.

Bond	Length	Dissociation Energy
single	1.47 Å	145 kJ/mol
double	1.24 Å	456 kJ/mol
triple	1.10 Å	945 kJ/mol

To Do

Students can use the bond lengths and bond dissociation energies to show the relationship between the number of shared electron pairs, bond length, and bond strength.

Important Compounds and Reactions

The approach to healing by traditional physicians during the renaissance was based on the existence of four humors (blood, phlegm, yellow bile, and black bile). Most traditional remedies were derived from plants. Apothecaries and other followers of Paracelsus used inorganic compounds as treatments. For example, a mixture used to treat fever contained powdered nitre (potassium nitrate), carbonate of potash (potassium carbonate), antimonial wine (hydrated potassium antimonyl tartrate), and sweet spirits of nitre (ethyl nitrate).

To Do

Help students write balanced equations for the reactions in the Ostwald Process.

$4NH_3(g) + 5O_2(g) \rightarrow 4NO(g) + 6H_2O(g)$

$2NO(g) + O_2(g) \rightarrow 2NO_2(g)$

$3NO_2(g) + H_2O(l) \rightarrow 2H^+(aq) + 2NO_3^-(aq) + NO(g)$

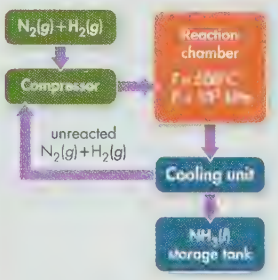
Group 5A

N Ammonia

Haber reacted three-to-one molar mixtures of hydrogen and nitrogen at different conditions of temperature and pressure. The yield of ammonia at equilibrium decreased with an increase in temperature and increased with an increase in pressure. Because the boiling point of ammonia (–33°C) is much higher than the boiling points of nitrogen (–196°C) or hydrogen (–253°C), it is possible to remove the ammonia from the equilibrium mixture and drive the reaction to completion.

The Haber process is sometimes called the Haber-Bosch process. Karl Bosch implemented Haber's process on an industrial scale. It was Bosch who found a catalyst that was cheaper and more available than the osmium and uranium that Haber had used. His team had to develop a furnace that could operate safely at the required temperature and pressure. In 1931, Bosch and Friedrich Bergius were awarded a Nobel Prize for the "invention and development of chemical high pressure methods."

Before the Haber Process, deposits of dried guano in Chile were the main source of fixed nitrogen. (The guano was deposited by fish-eating sea birds.) During World War I, a naval blockade of South America prevented Germany from importing the nitrates it needed to manufacture explosives. It has been argued that World War I would have ended sooner if Haber had not developed his process. Because Haber (as chief of Germany's Chemical Warfare Service) permitted the use of chlorine gas as a weapon, the awarding of his Nobel Prize in 1918 was controversial.



N Ammonia

The nitrogen in air is not in a form that is useful for plants. Natural sources of usable nitrogen in soil aren't sufficient to support current levels of crop production. A German chemist named Fritz Haber came up with a solution. He figured out how to convert atmospheric nitrogen into ammonia. In the Haber process, nitrogen and hydrogen are heated under pressure in the presence of iron.

$$N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g) \qquad \Delta H = 46.19 \text{ kJ/mol}$$

The ammonia is liquefied. Liquid ammonia, aqueous solutions of ammonia, and ammonium salts are used as fertilizers. Liquid ammonia is also used as a refrigerant. Many cleaning products contain aqueous ammonia, which is a weak base. Ammonia is also used to manufacture explosives.

Haber Process

When the reaction mixture is cooled, the liquified ammonia can be separated from the nitrogen and hydrogen.

N Explosives

Explosions are extremely rapid exothermic reactions that produce gaseous products. The most forceful explosions occur when the reactants are liquids or solids. Pressure builds up as the reactants are converted to gases, especially if the gases are confined. When the gases expand, the resulting release of pressure causes a shock wave. The kinetic energy of this wave, the wind that follows it, and the heat is the destructive force of the explosion.

Engineers use a series of small controlled explosions to force a building to collapse inward, or implode.

An explosion requires fuel and an oxidizer. If the oxidizer and fuel are separate, the reaction is a combustion reaction. This type of explosion could occur if natural gas leaking in a building was ignited by a spark or flame.

$$CH_4 + 2O_2(g) \longrightarrow CO_2(g) + 2H_2O(g) \qquad \Delta H = 890 \text{ kJ/mol}$$

If the fuel is its own oxidizer, a decomposition reaction takes place. Nitroglycerine, $C_3H_5(NO_3)_3$, is a thick, pale, oily liquid. It decomposes to form a mixture of gaseous products.

$$4C_3H_5(NO_3)_3(l) \longrightarrow 6N_2(g) + O_2(g) + 12CO_2(g) + 10H_2O(g) \qquad \Delta H = -1427 \text{ kJ/mol}$$

Self-oxidizing explosives are often unstable. Jarring them may be enough to cause detonation. Alfred Nobel, a Swedish chemist and inventor, found a way to use nitroglycerine with less risk. After his family's nitroglycerine factory exploded in 1864, he moved his experiments to a barge in the middle of a lake. One day he found a cask of nitroglycerine that had leaked. Luckily, the diatomite in which the cask was packed had absorbed the liquid. Nobel found that the mixture was stable until detonated by a blasting cap. Plus, the mixture was as explosive as the pure liquid. Nobel named his invention dynamite.

In his will, Nobel established a fund to provide annual prizes in chemistry, physics, physiology and medicine, literature, and peace.

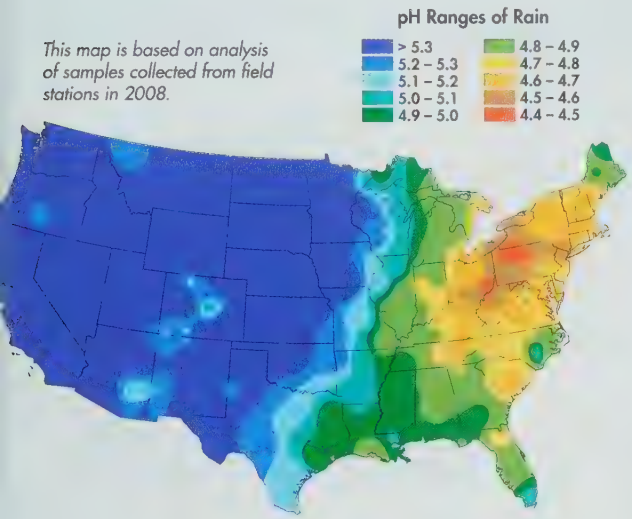
N Explosives

An explosion is highly exothermic when the bonds in the explosive are relatively weak and the bonds in the products are relatively strong. Because the bonds in N_2, CO, and CO_2 are very strong, many explosives are organic molecules with nitro or nitrate groups, which can react to produce N_2, CO, or CO_2.

Nitroglycerin is used to treat angina. Its effect is to cause blood vessels to dilate. The nitroglycerin used in pills, sprays, and patches is very dilute. Nitroglycerin has a short shelf life. It is unstable and must be stored in containers that prevent exposure to light.

N Acid Rain

Normal rainfall has a pH of about 5.6. It is mildly acidic because carbon dioxide in the air dissolves in tiny water droplets and forms carbonic acid (H_2CO_3). In acid rain, the pH is lower due to the emission of nitrogen oxides and sulfur oxides into the atmosphere. Some natural sources, such as volcanoes, emit these oxides. But most come from the burning of fossil fuels. In the atmosphere, the oxides form nitric acid (HNO_3) and sulfuric acid (H_2SO_4), which fall to Earth in rain or snow.



Because acid rain dissolves and washes away nutrients from soil, trees are dying in the Appalachian Mountains. Because aquatic species are highly sensitive to changes in pH, some lakes once full of fish and frogs are nearly lifeless.

Power plants are one source of sulfur oxides and nitrogen oxides. Devices called scrubbers are used to remove these pollutants from smoke. In one type of scrubber, smoke passes through an aqueous suspension of lime (CaO). The lime reacts with SO_2 to form solid calcium sulfite ($CaSO_3$).

Another type of scrubber can be used to remove nitrogen oxides. Ammonia is sprayed onto a surface covered with a mixture of catalysts. As smoke passes over the surface, nitrogen oxides react with ammonia and oxygen, forming nitrogen and water.

Another way to deal with nitrogen oxides is to keep them from forming in the first place. The method involves burning a fuel, such as coal, at a high temperature. When the burner contains more fuel than air, most of the oxygen in the air reacts with the fuel rather than the nitrogen.

This map is based on analysis of samples collected from field stations in 2008.

N P Fertilizers

Most fertilizers contain salts of nitrogen, phosphorus, and potassium. These elements are essential to plant growth. On the label, the percents by mass of these nutrients are always listed in the order N-P-K.

Because the salts in a fertilizer can vary, there are rules for reporting the content. Nitrogen is always reported as the percent by mass of elemental nitrogen. Phosphorus and potassium are reported as the percent by mass of phosphorus pentoxide, P_2O_5, and potassium oxide, K_2O.

This system makes it easy to compare fertilizers. For example, a fertilizer labeled 20-10-10 has twice the mass of nitrogen as one labeled 10-10-10. But they both have the same mass of phosphorus and potassium. The numbers may not add up to 100% because fertilizers always contain ingredients not included in the N-P-K analysis.

Did You Know?

If nail polish or lipstick contains **bismuth** oxychloride (BiOCl), it appears lustrous and pearly.

N Acid Rain

Acid rain has had a major impact on the ecology of lakes. Most lakes in which organisms live have a pH between 6.5 and 8.5. All of the vertebrates, most of the invertebrates, and many microorganisms cannot survive at a pH below 4.0. Lakes that are most likely to have a serious drop in pH due to acid rain are those with low concentrations of ions such as HCO_3^-, which can act as a buffer.

To Do

Have students use the isopleth map to determine the pH of rainfall in your region as of 2008. (An isopleth is a line connecting points on a graph or map that have equal values for a given variable.) Students can research trends by viewing the isopleth maps produced annually by the National Atmospheric Deposition Program (NADP).

N P Fertilizers

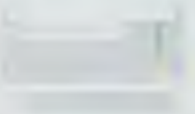
Mineral plant nutrients can be classified as primary nutrients (N, P, and K), secondary nutrients (Ca, Mg, and S), and micronutrients (B, Cu, Fe, Cl, Mn, Mo, and Zn). Primary and secondary nutrients tend to be less available to plants in soils with a low pH, but micronutrients tend to be more available to plants in soils with a high pH. Most plants do well in soil with a pH between 6.0 and 7.5.

To Do

Invite an expert to talk to the class about why fertilizers with different percent compositions are used with different types of plants or at different stages in plant growth.

Group 6A

Physical Properties



When molten sulfur cools below 119°C, it forms crystals of monoclinic sulfur. This allotrope contains eight-member rings of covalently bonded sulfur atoms (S_8). Below 95.5°C, the sulfur changes to rhombic sulfur, which is also composed of S_8 units. If molten sulfur is poured into cold water, an amorphous form of sulfur results. Within hours, the amorphous sulfur loses its elasticity as it is converted to rhombic crystals, which are more stable. Sulfur can be purified through boiling and condensation. Tiny rhombic crystals in flowerlike patterns form on the wall of the condensation chamber. The powder is known as flowers of sulfur.

Sources

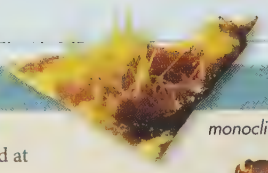
Some of the world's richest deposits of elemental sulfur are on the Gulf Coast in Louisiana and Texas. These deposits are not easily mined because they are buried under several hundred feet of quicksand. Herman Frasch (1851-1914) devised an ingenious method for getting sulfur out of the ground. The method takes advantage of sulfur's low melting point.

Wells are drilled into the sulfur bed. Three concentric tubes (with 2.5-cm, 7.5-cm, and 15-cm diameters) are installed. Compressed air and superheated water are pumped through the inner and outer tubes. The molten sulfur that emerges from the center tube is pumped into large storage vats where it cools and solidifies into huge blocks, which can be 130 m long, 70 m wide, and 30 m high. Dynamite is used to break up the blocks of sulfur for shipping.

GROUP 6A

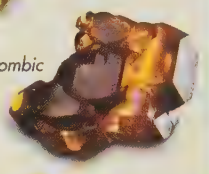
Oxygen discovered in 1772 by Carl Scheele and in 1774 by Joseph Priestly

Sulfur known since ancient times



Selenium discovered in 1817 by Jöns Jacob Berzelius

Tellurium discovered in 1782 by Franz Joseph Müller von Reichenstein

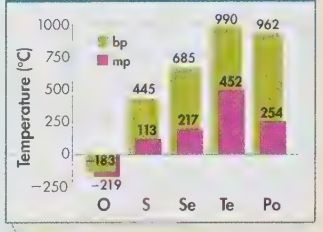


Polonium discovered in 1898 by Marie Curie

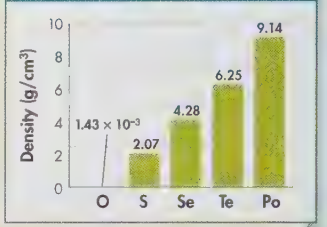
Physical Properties

- Except for oxygen gas, O_2, Group 6A elements are solid at room temperature.
- The metallic properties of Group 6A elements increase from top to bottom within the group.
- Polonium is a radioactive metal.

monoclinic



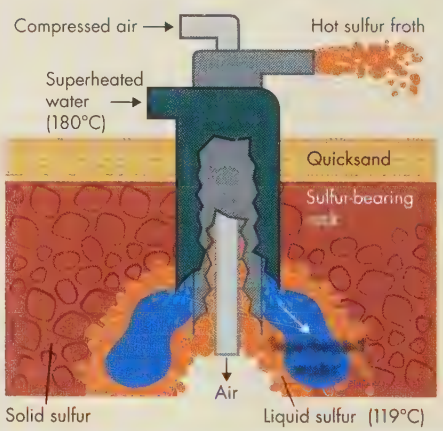
orthorhombic



The unit cell in crystalline sulfur is an S_8 molecule.

Melting and Boiling Points

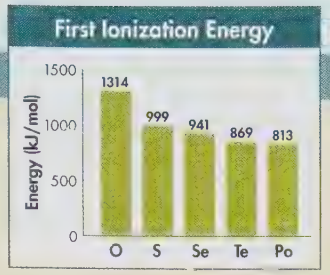
Density



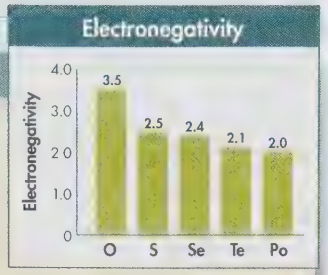
Sources

- Large-scale production of oxygen is by fractional distillation of liquid air. Liquid oxygen is stored and shipped at its boiling point of −183°C in vacuum-walled bottles.
- The Frasch process is used to mine sulfur from underground deposits. A well is drilled into a sulfur bed and a set of concentric tubes installed. Superheated water melts the sulfur. Compressed air forces it to the surface.
- Sulfur is also produced from hydrogen sulfide, H_2S, and sulfur dioxide, SO_2.

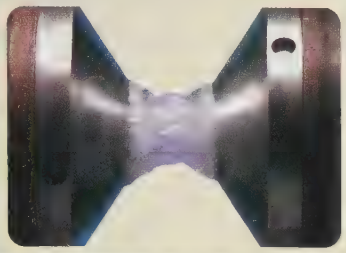
$$2H_2S(g) + SO_2(g) \longrightarrow 2H_2O(l) + 3S(s)$$



- Selenium and tellurium are by-products of the processing of sulfide ores for other metals.
- Polonium is formed by the radioactive decay of radium in minerals such as pitchblende.



The Frasch Process



Atomic Properties

- Group 6A elements have an electron configuration that ends in ns^2np^4.
- For Group 6A elements, the most common oxidation numbers are +4, +6, and −2.
- Oxygen is paramagnetic because there are unpaired electrons in O_2 molecules.

	O	S	Se	Te	Po
Atomic radius (pm)	66	105	120	139	168
Ionic radius (pm)	140 O^{2-}	184 S^{2-}	198 Se^{2-}	221 Te^{2-}	94 Po^{4+}

Liquid oxygen is held between the poles of a magnet because of its attraction to the magnet.

Important Compounds and Reactions

- Oxygen reacts with almost all other elements to form oxides. Example:

  $4K(s) + O_2(g) \longrightarrow 2K_2O(s) \quad \Delta H = -363.2$ kJ/mol
- Ozone, O_3, is produced directly from oxygen, O_2, during lightning strikes.

  $3O_2(g) \longrightarrow 2O_3(g) \quad \Delta H = +285$ kJ/mol
- Oxygen is necessary for releasing energy from fuels, such as glucose, in organisms.

  $C_6H_{12}O_6(s) + 6O_2(g) \longrightarrow 6CO_2(g) + 6H_2O(g) \quad \Delta H = -2808$ kJ/mol
- Oxygen is used to produce steel and to oxidize hydrogen in fuel cells.
- Sulfur compounds often have unpleasant odors. Hydrogen sulfide, H_2S, smells like a rotten egg. It forms when metallic sulfides and hydrochloric acid react. Example:

  $FeS(s) + 2HCl(aq) \longrightarrow H_2S(g) + FeCl_2(aq)$
- Concentrated sulfuric acid, H_2SO_4, is a strong dehydrating agent. Example:

  $C_{12}H_{22}O_{11}(s) \xrightarrow{H_2SO_4} 12C(s) + 11H_2O(g)$

When concentrated sulfuric acid is added to sucrose, water vapor and carbon are produced. The release of the vapor causes the carbon to expand.

- Ethyl mercaptan, CH_3CH_2SH, is commonly called "stench." It is added to supplies of odorless natural gas so people will know when the gas is leaking.
- Sodium thiosulfate, $Na_2S_2O_3$, also known as *hypo*, is used in the development of dental X-rays.
- The addition of cadmium selenide, CdSe, gives glass a beautiful ruby color.

Atomic Properties

Students may think that only metals can be affected by a magnetic field. Explain that substances in which all electrons are paired are diamagnetic, i.e., weakly repelled by an external magnetic field. Substances in which there are unpaired electrons are paramagnetic, i.e., attracted to an external magnetic field. The more unpaired electrons, the stronger the force of attraction.

Important Compounds and Reactions

Concentrated sulfuric acid dissolves readily in water. The process is highly exothermic. The ΔH_{soln} for sulfuric acid is −95.28 kJ/mol. The strong affinity of sulfuric acid for water makes sulfuric acid a powerful dehydrating agent, as demonstrated by its effect on sucrose.

Each odorant has a detection threshold, or concentration at which 50% of people can identify the presence of the odor. Ethyl mercaptan's detection threshold is 0.0026 ppm, which is relatively low. Because olfactory acuity, or the ability to detect odors, tends to decrease with age, many elderly people are unable to detect ethyl mercaptan at its concentration in natural gas. Sulfur compounds with unpleasant smells are generally classified as putrid.

Group 6A

Se Selenium in Food

Keratin is the principal protein in the hoofs and hair of horses, as it is in human hair. Sulfur-containing thiol groups in the amino acid cysteine form the disulfide bonds between adjacent protein chains. Selenium can be substituted for sulfur when present in excess. Chronic selenium poisoning in horses is often called "bob-tail disease" because hair in the mane and tail breaks at the location in the hair shaft where selenium is substituted for sulfur.

S Sulfuric Acid

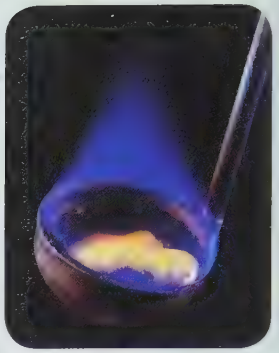
For a long time, researchers were unable to determine how the conversion of sulfur dioxide to sulfur trioxide, which is normally a slow process, occurred so rapidly in air. Research has since shown that dust and other solid particles in the air act as a catalyst for the process.

GROUP 6A

Se Selenium in Food

Selenium is an antioxidant that protects cell membranes from damage. In the United States, grain is grown on selenium-rich soils. Livestock and people who eat those grains are unlikely to be deficient in selenium.

An essential nutrient may be harmful in large doses. Too much selenium can damage the nervous system. It may also cause anxiety and fatigue.



This milkvetch (Astragalus bisulcatus) accumulates high levels of selenium.

Soils in the Great Plains and Rocky Mountain regions often contain high levels of selenium. If cattle graze on plants that grow in those soils, they may develop chronic selenium poisoning. The symptoms include loss of hair, sore hoofs, lameness, and a lack of energy.

Acute selenium poisoning causes cattle to lose their vision and stumble aimlessly before dying from respiratory failure. Cowboys called this condition the "blind staggers."

S Sulfuric Acid

When sulfur burns in air, the product is the irritating gas sulfur dioxide, SO_2.

Pure sulfuric acid is a dense, colorless, oily liquid. Concentrated sulfuric acid is 98% H_2SO_4 and 2% H_2O. Dilute sulfuric acid reacts with metals, oxides, hydroxides, or carbonates to form sulfates. The reaction with metals also releases hydrogen gas. Sulfuric acid can be used to produce other acids from their salts. For example, hydrogen chloride can be produced from sulfuric acid and sodium chloride.

$$H_2SO_4(l) + 2NaCl(s) \longrightarrow Na_2SO_4(s) + 2HCl(g)$$

Sulfuric acid is produced mainly from sulfur dioxide. The process is called the contact process because the key reaction takes place when the reactants are in contact with the surface of the solid catalyst.

(1) Melted sulfur is burned in air.

$$S(l) + O_2(g) \longrightarrow SO_2(g)$$

(2) Sulfur dioxide is oxidized in the presence of a vanadium oxide catalyst, V_2O_5.

$$2SO_2(g) + O_2(g) \xrightarrow{V_2O_5} 2SO_3(g)$$

(3) Sulfur trioxide dissolves in water and forms sulfuric acid.

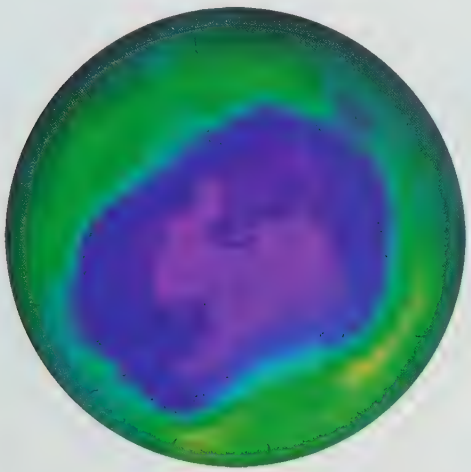
Much of the sulfuric acid produced in North America is used to make fertilizers. Sulfuric acid is also used in petroleum refining, the production of other chemicals, and for pickling iron and steel. During pickling, oxides are removed from the surface of a metal.

This marine slug of the species Berthella martensi produces sulfuric acid, which discourages predators.

R26 Elements Handbook

O Ozone

Near Earth's surface, ozone (O_3) is a pollutant. In the stratosphere, ozone is literally a lifesaver. The ozone layer in the stratosphere absorbs 99% of the sun's harmful ultraviolet (UV) radiation. In the 1970s, scientists began to suspect that the ozone layer might be threatened. They based their concerns on laboratory models. In 1985, their suspicions were confirmed when British researchers discovered a "hole" in the ozone layer over Antarctica. In the winter, the amount of ozone was reduced by almost one half.



The scientists traced the thinning of the ozone layer to chemicals called chlorofluorocarbons (CFCs). These chemicals were used mainly as propellants in aerosol spray cans and as coolants in refrigerators and air conditioners. CFCs are highly stable and inert in the lower atmosphere. Over time, they drift up into the stratosphere, where they are broken down by solar radiation. Through a repeated cycle of reactions (2) and (3), a single chlorine atom can destroy as many as 100,000 molecules of ozone.

(1) $CCl_3F \longrightarrow Cl\bullet + \bullet CCl_2F$

(2) $Cl\bullet + O_3 \longrightarrow ClO\bullet + O_2$

(3) $ClO\bullet + O \longrightarrow Cl\bullet + O_2$

In 1978, the United States banned the use of CFCs in aerosols. In 2007, most countries agreed to stop producing CFCs by 2020. The ban has had an effect. Concentrations of CFCs have begun to level off in the stratosphere and even decline in the lower atmosphere.

In September 2006, the "hole" over Antarctica was record size. The amount of ozone is low in the blue areas. It may take decades for the ozone layer to reach pre-1980 levels.

S Thiols

Skunks use a foul-smelling liquid to repel predators. The compounds in the mixture are mainly sulfur-containing molecules. One type of sulfur compound called a thiol is responsible for the foul odor. Thiols are organic compounds in which the oxygen of an alcohol has been replaced by sulfur. The general formula for a thiol is RSH.

The foul liquid is secreted and stored in glands until the skunk feels threatened. When it is threatened, the skunk contracts the muscles around the glands and sprays the liquid in the direction of the threat. A skunk can propel the liquid for about three meters! Other than smelling bad for a while, the "attacker" is not harmed.

Did You Know?

Organic compounds containing **sulfur** give onions their taste and smell. When an onion is cut, reactions occur that produce propanethial-S-oxide. When receptors in your eyes are exposed to this irritating gas, they trigger the production of tears.

O Ozone

As sunlight travels through the ozone layer, ozone absorbs light of known wavelengths. The amount of light of these wavelengths that passes through the atmosphere is an indication of the amount of ozone present. In 2003, researchers at the University of Alabama in Huntsville used such data collected by NASA Earth-observing satellites to show that the rate of ozone depletion in the upper stratosphere had slowed since 1997.

When CFCs are broken down by solar radiation, they release chlorine atoms. A chlorine atom can destroy as many as 100,000 molecules of ozone because it is a free radical. A free radical is very reactive because it contains one or more unpaired electrons.

To Do

Encourage interested students To Do additional reading on the research that led to the Montreal Protocol, which established an international ban on CFC-based products.

S Thiols

Ask students if they have had to deal with a pet that was sprayed by a skunk, and, if so, what approach they used. Students may say that they washed the pet with tomato juice, followed by a vinegar rinse. This traditional remedy doesn't actually remove the source of the odor. Rather, it masks the odor.

A better approach is based on an industrial method for scrubbing sulfur-containing compounds from waste gas streams in coal-burning power plants. The pet is washed with a mixture of hydrogen peroxide, baking soda, and liquid soap. The soap breaks up the oils in the spray. The hydrogen peroxide and baking soda react and produce oxygen, which reacts with the thiols.

Group 7A

Physical Properties

Astatine comes from the Greek *astatos,* meaning "unstable." It was synthesized by bombarding bismuth with alpha particles. Astatine-210 is the longest-lived isotope with a half-life of 8.3 hours. Despite the small quantities available for study, some properties of astatine have been demonstrated, including its ability to dissolve more easily in organic solvents than in water.

Sources

It was difficult for chemists to isolate fluorine because fluorine is such as strong oxidizing agent. The task was further complicated by the toxicity of hydrogen fluoride. Many chemists, including Davy and Gay-Lussac, suffered health problems from their attempts to prepare fluorine. The process Henri Moissan used to prepare fluorine (electrolysis of a solution of potassium fluoride in hydrogen fluoride) is the process used today.

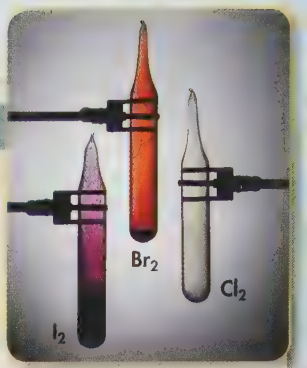
To Do

Invite a mineral collector to class to show off samples of fluorite, which is second only to quartz in its popularity with collectors. You could use the visit to discuss crystal systems.

GROUP 7A

Fluorine discovered in 1886 by Henri Moissan

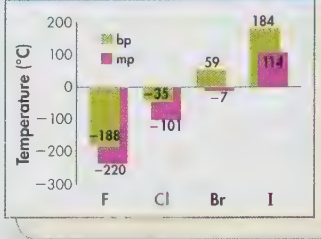
Chlorine discovered in 1774 by Carl Wilhelm Scheele



Bromine discovered in 1826 by Antoine-Jérôme Balard

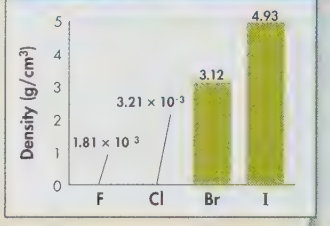
Iodine discovered in 1811 by Bernard Courtois

Astatine discovered in 1940 by Dale R. Corson, K. R. Mackenzie, & Emilio Segrè



Physical Properties

- Halogens are nonmetals. At room temperature, fluorine and chlorine are gases and bromine is a liquid. Iodine and astatine are solids.
- Halogens are very reactive. The reactivity decreases from fluorine to astatine. Halogens do not exist in the elemental form in nature.
- Astatine isotopes are radioactive with short half-lives.



The colorful vapors of bromine and iodine are visible because bromine is volatile and iodine sublimes easily at room temperature.

Melting and Boiling Points

Density

Sources

- Chlorine gas is made commercially by the electrolysis of brine.

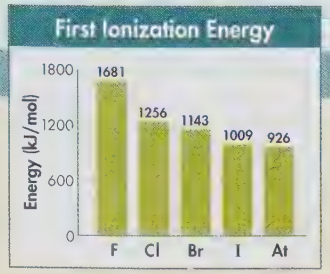
$$2NaCl(aq) + 2H_2O(l) \longrightarrow Cl_2(g) + H_2(g) + 2NaOH(aq)$$

- Bromine is obtained from seawater by a displacement reaction with chlorine.

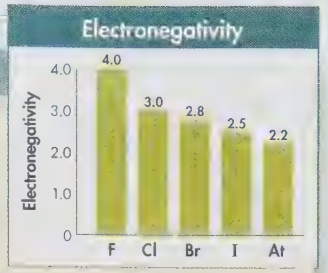
$$2NaBr(aq) + Cl_2(g) \longrightarrow 2NaCl(aq) + Br_2(l)$$

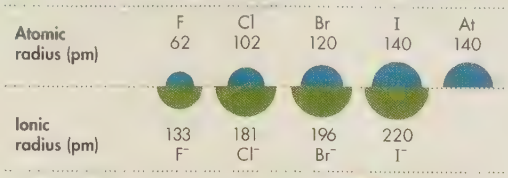
- Iodine is found in brine and in sodium iodate, $NaIO_3$, in deposits of sodium nitrate. Iodine is produced from $NaIO_3$ by this redox reaction.

$$2NaIO_3(aq) + 5NaHSO_3(aq) \longrightarrow I_2(g) + 2Na_2SO_4(aq) + 3NaHSO_4(aq) + H_2O(l)$$



- Fluorine is manufactured by the electrolysis of potassium fluoride, KF, dissolved in liquid hydrogen fluoride, HF.





Fluorite, CaF_2, is the principal mineral of fluorine. The term fluorescent comes from this mineral, which glows in the presence of UV radiation.

Atomic Properties

- Group 7A elements have an electron configuration that ends in ns^2np^5.
- Halogens exist as diatomic molecules.
- Each halogen has the highest electronegativity in its period.
- The most common ionic charge for halogens is 1−. Except for fluorine, halogens also have positive oxidation numbers of +1, +3, +5, and +7.

Chlorine forms four anions with oxygen. The oxidation number of chlorine is different in each anion.

Hypochlorite ion Chlorite ion Chlorate ion Perchlorate ion

Important Compounds and Reactions

- Halogens form metal halides. Example:

  $2Na(s) + Cl_2(g) \longrightarrow 2NaCl(s) \quad \Delta H = -411$ kJ/mol

- Halogens form hydrogen halides. Example:

  $H_2(g) + Cl_2(g) \longrightarrow 2HCl(g) \quad \Delta H = -92.3$ kJ/mol

- Dry bleach is a mixture of compounds represented by the formula CaCl(ClO). Dry bleach is used to bleach paper and textiles. It also removes stains and disinfects laundry.

  $Ca(OH)_2(aq) + Cl_2(g) \longrightarrow CaCl(ClO)(aq) + H_2O(l)$

- Small amounts of oxygen are produced in the laboratory by heating potassium chlorate, $KClO_3$. Potassium chlorate is an oxidizing agent in fireworks, matches, and explosives.

  $2KClO_3(s) \longrightarrow 2KCl(s) + 3O_2(g)$

- Canisters of sodium chlorate are used on submarines to produce oxygen. They are carried on airplanes in case of an emergency.
- Chlorine is used to make the monomer vinyl chloride, $CH_2 = CHCl$, which reacts to form the polymer polyvinyl chloride (PVC).

Chlorine reacts vigorously with sodium to form solid sodium chloride.

- Hydrofluoric acid (HF) is made from the mineral fluorite and sulfuric acid. Although HF is extremely dangerous, it has many uses, including cleaning metals and frosting glass.

  $CaF_2(s) + H_2SO_4(aq) \longrightarrow 2HF(g) + CaSO_4(s)$

- Nonstick pans are coated with a polymer of tetrafluoroethene, $F_2C = CF_2$.
- Tincture of iodine is a solution of iodine, I_2, and potassium iodide, KI, in alcohol. It is an example of an iodine-based skin disinfectant.

Atomic Properties

The ball-and-stick models of the anions containing chlorine and oxygen could prove useful when students study VSEPR theory in Chapter 8.

To Do

Ask students to calculate the oxidation number of chlorine in the hypochlorite, chlorite, chlorate, and perchlorate ions.

Important Compounds and Reactions

Finding a container to store elemental fluorine was a challenge because fluorine attacks glass and causes most metals to burst into flame. Alloys of copper and nickel are used because when fluorine reacts with the alloy, it forms a protective (passive) fluoride layer on the surface.

Fluorine is used to enrich uranium. Fluorine reacts with uranium to produce the gas uranium hexafluoride (UF_6). Because the rate of diffusion of the gas varies with the isotope, uranium-235 (the fissionable isotope) can be separated from uranium-238.

To Do

Challenge students to explain why HCl, HBr, and HI form strong acids when dissolved in water, but HF forms a weak acid. (The strong hydrogen bonds between the polar HF molecules limit the ionization of hydrogen fluoride in water.) Then challenge students to find out why concentrated hydrofluoric acid, is extremely dangerous. (Hydrofluoric acid causes severe painful burns on contact with body tissues. Because of the small size of its molecules, hydrofluoric acid can penetrate skin and fat quickly. It decalcifies bone and acts as a poison once it is in the blood.)

Group 7A

F Tooth Decay

Low concentrations of fluoride ions are present in all natural water sources, but the level may not be sufficient for the prevention of tooth decay. In the United States, the optimum concentration for fluoride in water supplies is in the range of 0.7 to 1.2 ppm.

Because fluoride ions are toxic in high concentrations, FDA regulations limit the amount of fluoride in toothpaste. Even so, people should rinse away excess toothpaste. There is a warning on toothpaste labels about the use of toothpaste by children under 6 years of age. Young children need to be supervised until they have learned how to minimize the ingestion of toothpaste.

Cl Swimming Pool Chemistry

Students may wonder why the chlorine that kills bacteria doesn't harm humans who use a swimming pool. The answer lies with the concentration.

To Do

In the early 1900s, health officials in developed countries began to use chlorine to treat drinking water. Students could research the effect that adding chlorine to drinking water had on outbreaks of diseases such as cholera, typhoid fever, and dysentery, which are caused by waterborne pathogens.

F Tooth Decay

Your teeth have a hard outer layer called enamel. This layer is mainly calcium carbonate, $CaCO_3$, and hydroxyapatite, $[Ca_3(PO_4)_2]_3 \cdot Ca(OH)_2$.

Lactic acid, $C_3H_6O_3$, is the main cause of tooth decay. It forms when bacteria in saliva feed on sugars present in the sticky plaque on tooth surfaces. An increase in H^+ concentration causes the minerals in tooth enamel to decay faster. One source of this increased acidity is the phosphoric acid in soft drinks.

Fluoride ions are added to the water supply in many cities. Most toothpastes contain fluoride ions. The ions replace hydroxide ions in hydroxyapatite to form fluoroapatite, $[Ca_3(PO_4)_2]_3 \cdot CaF_2$. This replacement makes the enamel more resistant.

Fluoride ions alone will not prevent tooth decay. You need to brush your teeth and floss to keep plaque from building up on your tooth enamel.

Cl Swimming Pool Chemistry

The person who maintains a swimming pool has two main goals. Prevent the growth of bacteria that cause diseases. Prevent the growth of algae that can foul the water and clog the filters. Chlorine compounds are used to disinfect pool water. "Liquid chlorine" contains sodium hypochlorite, NaClO. "Dry chlorine" is calcium hypchlorite, $Ca(ClO)_2$. When hypochlorite ions dissolve in water, hydrolysis occurs and weak hypochlorous acid, HClO, is produced.

$$ClO^-(aq) + H_2O(l) \rightleftharpoons HOCl(aq) + OH^-(aq)$$

The amount of undissociated hypochlorous acid in the pool water depends on the pH. If the pH is too high, the hydrolysis reaction will shift toward the reactants and reduce the concentration of HClO. If the pH is too low, too much acid will form. A high concentration of acid can cause eye irritation, damage plaster, and corrode the metal piping and filters in the pool.

If the pH of the pool water is too high, solid sodium hydrogen sulfate can be used to react with the OH^- ions.

$$NaHSO_4(s) + OH^-(aq) \longrightarrow Na^+(aq) + SO_4^{2-}(aq) + H_2O(l)$$

If the pH is too low, sodium carbonate can be used to neutralize some of the acid.

$$Na_2CO_3(s) + 2H^+(aq) \longrightarrow 2Na^+(aq) + H_2O(l) + CO_2(aq)$$

The use of fluorides in drinking water and toothpastes has caused such a drastic reduction in tooth decay that many young adults have never had a cavity.

F Blood Substitutes

The most important function of blood is its ability to deliver oxygen from the lungs to cells throughout the body and carry carbon dioxide from the cells to the lungs. Blood transfusions have been the traditional response to blood loss due to severe injuries or surgery. Blood transfusions have saved millions of lives. But it takes time to determine the recipient's blood type and less common blood types may not be available. Also, blood can carry disease-causing bacteria and viruses.

Scientists have tried for years to develop an effective and profitable blood substitute. One approach focused on perfluorocarbons (PFCs). PFCs are organic compounds in which all the hydrogen has been replaced by fluorine. PFCs can dissolve and transport oxygen. They are fairly inexpensive to manufacture, their purity can be controlled, and they don't react with other substances in the body.

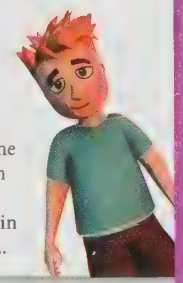
Some problems with PFCs were revealed during clininal trials. Because PFCs are insoluble in water, they must be mixed with lipids to form an emulsion. The emulsion can be unstable in blood, which means that it is not effective for long. Because PFCs carry less oxygen than hemoglobin does, the patient must breathe oxygen-rich air.

Because blood is so complex, scientists may never find a substitute to perform all its functions. Therefore, there is still a great need for donations of human blood.

Hemoglobin is the molecule in red blood cells that transports oxygen. For a blood substitute to be effective, it has to perform this same function.

I Iodized Salt

The thyroid gland produces hormones that help to control the body's growth and the energy produced by cells. Trace amounts of iodine are needed to produce thyroid hormones. An adult needs about 150 mg of iodine daily.



Ocean fish are a good source of iodine. When people used to get most of their food from local sources, a person who lived far from the ocean often had an iodine deficiency. To compensate for the lack of iodine, the thyroid gland might enlarge. A severe deficiency causes some forms of mental disability. Adding potassium iodide to table salt proved to be a simple solution to this public health problem.

In the United States, iodized salt was first sold in 1924. There is about 400 mg of iodine in a teaspoon of iodized salt. The use of iodized salt has virtually eliminated the problem of iodine deficiency in the United States.

Did You Know?

The purple dye prized by Roman emperors and other rulers contained **bromine** in the compound 6,6'-dibromoindigo. The dye was extracted from the mollusk *Murex brandaris*, which lives in the Mediterranean Sea.

F Artificial Blood

The term *blood substitute* is a bit misleading because the substitutes generally perform only one function of blood. A more accurate description would be "Cell-free oxygen carriers." The ideal oxygen carrier (1) would not require refrigeration, (2) could be used with all blood types, (3) would be free of infectious agents, and (4) would be easy to use.

To Do

Use the discussion of blood substitutes as an antidote to the idea that scientific research is a series of success stories. So far, blood substitutes, whether PFC-based or hemoglobin-based, have had limited success despite the time and money invested.

I Iodized Salt

Recipes that call for large quantities of table salt often specify non-iodized salt. Some cooks claim large amounts of potassium iodate affect the flavor of food. In other cases, the issue is not the iodine, but other additives, e.g., non-caking agents, that the user is trying to avoid.

To Do

Table salt manufacturers in the United States use potassium iodide. But in countries where the climate is hot and humid, potassium iodate may be used instead. Challenge students to find data to demonstrate why potassium iodate might be preferable to potassium iodide in hot, humid climates. (The solubility of potassium iodide is 148 g/100 g H_2O at 25°C; the solubility of potassium iodate is 9.22 g/100g H_2O at 25°C.)

Group 8A

The names of all the noble gases except radon come from Greek words. Helium comes from *helios,* meaning "sun." Xenon comes from *xenos*, meaning "strange." Krypton comes from *kryptos,* meaning "hidden." Argon comes from *argos,* meaning "inert." Neon comes from *neos,* or "new."

Physical and Chemical Properties

More than 80 compounds of xenon have been produced. Krypton forms the colorless solid krypton(II) fluoride, KrF_2. The compound of argon, argon fluorohydride (HArF), produced in 2000 exists only at temperatures below –246°C.

To Do

Show students how to draw an electron dot structure for xenon(II) fluoride (XeF_2). Then have students draw electron dot structures for xenon(IV) fluoride (XeF_4), xenon(IV) oxide (XeO_3), and xenon(VIII) oxide (XeO_4). As a further challenge, students could try drawing the electron dot structures for XeO_2F_2 or $XeOF_4$.

Sources

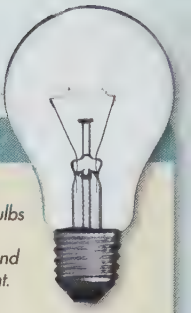
Although there are measurable amounts of radon in most regions of the United States, the highest levels are recorded in regions where the bedrock is granite. Radon is a product of the natural decay of uranium-238. Radon can seep through cracks in foundations and basements floors. Because it is denser than air, radon tends to collect in the lower levels of a house. Inhaling radon may increase the risk of lung cancer. High levels of radon can be reduced by improved ventilation in basements and other closed areas where radon collects.

GROUP 8A

Helium discovered in 1868 by Pierre Janssen

Neon discovered in 1898 by Sir William Ramsay & Morris Travers

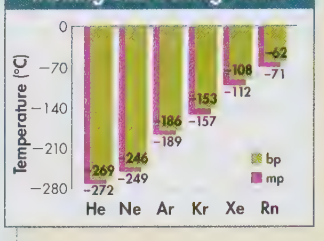
Argon discovered in 1894 by Lord Rayleigh & Sir William Ramsay



Krypton discovered in 1898 by Sir William Ramsay & Morris Travers

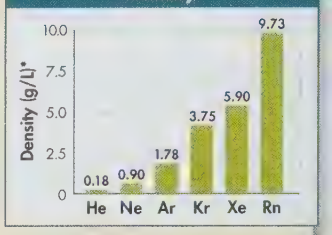
Xenon discovered in 1898 by Sir William Ramsay & Morris Travers

Radon discovered in 1900 by Friedrich E. Dorn



Physical and Chemical Properties

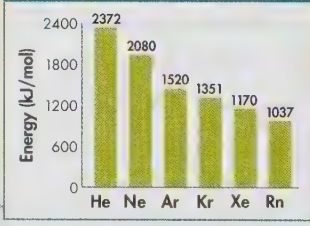
- All Group 8A elements are monatomic gases at STP.
- Noble gases are colorless, odorless, and tasteless.
- The first compound of a noble gas, $XePtF_6$, was made in 1962. More than 100 compounds of fluorine and xenon are now known.
- A compound of argon, HArF, exists only at temperatures below −246°C.



Incandescent light bulbs are filled with argon instead of air to extend the life of the filament.

Melting and Boiling Points

Density



*at STP

Atomic Properties

- Noble gases have an electron configuration that ends in ns^2np^6, except for helium ($1s^2$).
- In noble gas compounds, the most common oxidation number for the gas is +2.
- Noble gases have the highest ionization energies because their energy levels are filled.

First Ionization Energy

Each noble gas emits a characteristic color in a gas discharge tube.

Sources

- Helium is separated from natural gas deposits. Neon, argon, krypton, and xenon are separated from air by fractional distillation.
- Because of its low density, helium is used in weather balloons and airships.
- In addition to "neon" lights, noble gases are used in fluorescent bulbs, strobe lights, and headlights.
- Liquid helium cools the magnets used for magnetic resonance imaging (MRI).

Atomic Properties

The noble gases that form compounds most readily have larger atoms in which there are more electrons to shield the electrons in the highest occupied energy level from the nuclear charge.

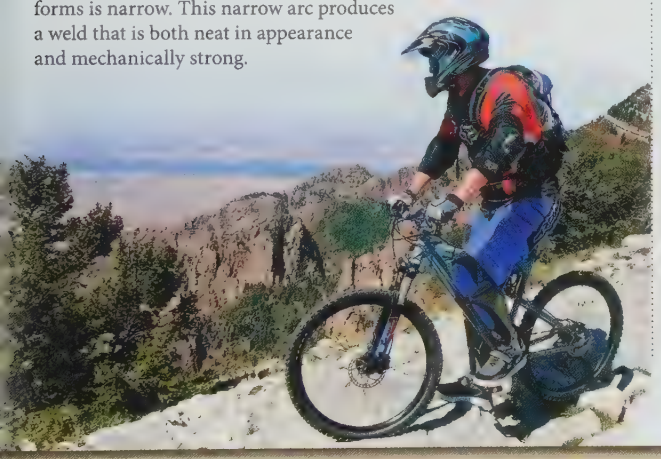
To Do

Encourage students to research the role of krypton-86 in the development of a definition for a meter. Ask them to determine why a definition based on krypton-86 was adopted in 1960 and why it was replaced in 1983.

Ne Neon Lights

By 1855, scientists could produce light by passing an electric current through a gas under low pressure in a sealed glass tube. With the discovery of the noble gases, a new technology emerged. In 1910, George Claude displayed the first neon lamp in Paris, France.

In 1923, a car dealer from Los Angeles bought two signs that spelled out "Packard" for $24,000 (about $250,000 in today's dollars). When he displayed the signs in Los Angeles, people described the light as "liquid fire." By the 1930s, businesses were using neon lights to draw the attention of customers.



Neon and argon are the gases most often used in neon lights. Orange-red lights contain only neon. Other colors are produced by adding a bit of mercury to the noble gas. The tube is coated with a material that glows when exposed to UV light emitted by mercury vapor.

Ar Taken For a Ride By Argon

Whether riding on a paved city street or on an unpaved mountain trail, a bicyclist is likely to find rough patches. When faced with rough terrain, the cyclist may worry about the tires, but probably not about the bicycle frame. The metal frames are made of steel, aluminum alloy, or titanium tubes that are joined together.

The tubes are joined together by Tungsten Inert Gas (TIG) welding. An electric arc is struck between a tungsten electrode and the parts to be welded. Heat from the arc melts the ends of the tubes and fuses them together. Filler may be placed between the ends of the tubes to increase the strength of the joint or to produce a smoother joint.

During welding in air, there is a danger that the metal tubes or electrode will oxidize. To prevent oxidation, the area around the arc is filled with an inert gas, most often argon. Welding with argon has an added benefit. Because argon is a poor conductor of heat, the arc that forms is narrow. This narrow arc produces a weld that is both neat in appearance and mechanically strong.

Xe Xenon-Ion Engine

The signals for a television program may bounce off a communication satellite. The satellite is in orbit above the equator. The position of the satellite may be maintained by a xenon-ion propulsion system.

When electrons strike xenon atoms in a xenon-ion engine, the atoms lose electrons and form positive ions. The ions are accelerated by a charged grid and shot from the engine at about 105 km/h. This action pushes, or thrusts, the satellite in the opposite direction. With multiple engines facing in different directions, a satellite can be moved in any direction.

Although a xenon-ion engine produces a relatively small amount of thrust, it can provide thrust for months or years. This makes xenon-ion engines a good choice for lengthy space missions. In addition, an inert gas poses no hazard for the satellite or the people who handle the propellant tanks.

Did You Know?

When liquid **helium** is cooled to below 2 K, its viscosity drops to zero. It will escape from an unsealed container by flowing up the sides of the container.

Ne Neon Lights

The development of neon lights can be traced back to an observation made by the French astronomer Jean Picard in 1675. He observed a faint glow in the tube of a mercury barometer when the tube was shaken.

Los Angeles in the 1930s was a low-rise city. Businesses used elaborate, art deco neon signs to attract motorists, who could see the signs from miles away. Many of the vintage signs have been restored. In 1949, Raymond Chandler wrote, "There ought to be a monument to the man who invented neon lights." (A monument to Claude might be a problem given his political choices. He was imprisoned from 1945–1949 for his support of the Vichy government in occupied France.)

Xe Xenon-Ion Engines

Because it completes one orbit in 24 hours, a communication satellite appears to be stationary above Earth. The altitude at which a satellite orbits Earth depends on its task. Stationary weather and communication satellites orbit at an altitude of about 22,300 miles. The region in which they orbit is called the Clarke Belt in honor of the science-fiction writer Arthur C. Clarke. Countries are assigned positions in the Clarke Belt for their communications and weather satellites.

Ar Taken For a Ride By Argon

Welders who use TIG must be aware of a safety issue. Breathing argon-rich air can deprive the body of oxygen. A person could pass out or even die from asphyxiation. So argon must be used in a well-ventilated room.

Hydrogen

Hydrogen was prepared long before it was recognized as a distinct substance. The Swiss alchemist Theophrastus Paracelsus probably handled hydrogen in the 1500s. He produced a flammable gas when he dissolved a metal in acid. In 1671, Boyle published a paper in which he described a reaction between iron filings and acids that produced "an inflammable gas." Cavendish described hydrogen as "inflammable air from metals." Lavoisier named hydrogen from the Greek *hydro,* meaning "water" and *genes,* meaning to "generate."

Atomic and Physical Properties

Giving unique names to isotopes is limited to the isotopes of hydrogen. Hydrogen is an exception to the rule that there are only minor differences in the physical properties of an element's isotopes. When a neutron is added to an atom with a single proton, the mass is doubled (or tripled when a second neutron is added). These relatively large differences in atomic mass contribute to greater differences in the physical properties of hydrogen isotopes and their compounds. For example, H_2O melts at 0°C and boils at 100°C; D_2O melts at 3.81°C and boils at 101.42°C.

Sources

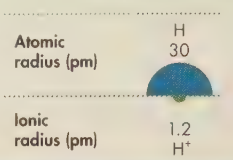
Much hydrogen is also obtained from petroleum refining. During refining, hydrogen is a by-product of the catalytic break down of large hydrocarbon molecules into smaller molecules.

Small quantities of hydrogen are prepared in the laboratory by the reaction of dilute acid with an active metal, such as zinc.

$Zn(s) + 2HCl(aq) \rightarrow H_2(g) + ZnCl_2(aq)$

Hydrogen

1 H Hydrogen 1.00/9



Hydrogen discovered in 1766 by Henry Cavendish

Atomic and Physical Properties

- Hydrogen has an electron configuration of $1s^1$.
- The most common oxidation numbers for hydrogen are +1 and −1.
- Most hydrogen (99.985%) is protium, or hydrogen-1.
- The other stable isotope is deuterium (hydrogen-2), which has the symbol D. Harold Urey discovered heavy hydrogen, D_2, in 1931.
- Tritium (hydrogen-3) was discovered in 1934. Its half-life is 12.3 years.

Properties of Hydrogen

Property	Value
Density at STP	0.09 g/L
Melting point	−259°C
Boiling point	−253°C
Ionization energy	1.312×10^3 kJ/mol
Electronegativity	2.1

Sources

- Hydrogen is rarely found on Earth in an uncombined state.
- Electrolysis of water produces the purest hydrogen, but the process requires too much energy to be economical.

$$2H_2O(l) \longrightarrow 2H_2(g) + O_2(g) \qquad \Delta H = +572 \text{ kJ}$$

- Hydrogen is produced when methane and steam react at 1100°C over a nickel catalyst.

$$H_2O(g) + CH_4(g) \xrightarrow{Ni} CO(g) + 3H_2(g) \qquad \Delta H = +206 \text{ kJ}$$

The products pass over a metal oxide catalyst at 400°C. As carbon monoxide reacts with added steam, more hydrogen is produced.

$$CO(g) + H_2O(g) \longrightarrow CO_2(g) + H_2(g) \qquad \Delta H = -41 \text{ kJ}$$

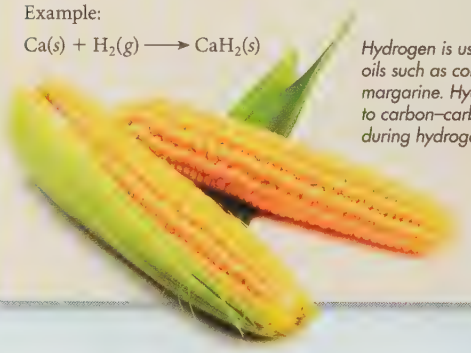
Carbon dioxide is removed as the gases flow through a basic solution.

$$CO_2(g) + 2OH^-(aq) \longrightarrow CO_3^{2-}(aq) + H_2O(l)$$

Atomic and Physical Properties

- Hydrogen forms molecular binary hydrides with nonmetals. Example:

$$H_2(g) + Cl_2(g) \longrightarrow 2HCl(g)$$



- Two thirds of the hydrogen produced in the U.S. is used to synthesize the molecular binary compound ammonia.
- Hydrogen forms ionic hydrides with alkali metals and alkaline earth metals. These hydrides are powerful reducing agents. Example:

$$Ca(s) + H_2(g) \longrightarrow CaH_2(s)$$

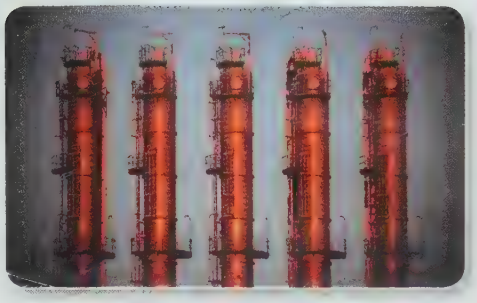
- Hydrogen is used to make methanol, CH_3OH. The reaction takes place at 200–300 atm and 400°C in the presence of a metal oxide catalyst.

$$CO(g) + 2H_2(g) \longrightarrow CH_3OH(g)$$

Methanol is an industrial solvent. It is used to make formaldehyde, CH_2O, which is used to make plastics.

Hydrogen is used to turn liquid oils such as corn oil into solid margarine. Hydrogen is added to carbon–carbon double bonds during hydrogenation.

Important Compounds and Reactions



The oxidation number of hydrogen in covalent binary hydrides is +1. With the exception of water, most low molar mass covalent binary hydrides are gases or liquids with low boiling points. The oxidation number of hydrogen in ionic binary hydrides is −1. These hydrides are white crystalline solids with high melting points. They are formed by direct reaction of alkali metals and alkaline earth metals with hydrogen at about 400°C.

To Do

Ask students to write equations for the dissociation of a covalent binary hydride and an ionic binary hydride in water. Then have them identify the reaction in which hydrogen is acting as a base (in the ionic hydride) and the reaction when hydrogen is acting as an acid. Note that the hydride ion is one of the strongest bases known.

H Heavy Water Reactors

Because 1 in 6400 hydrogen atoms is deuterium, 1 in 41 million water molecules is D_2O. D_2O is called heavy water because it is about 10% heavier than ordinary water. In heavy water nuclear reactors, D_2O is used in place of H_2O as a neutron moderator. Both types of water are good moderators, but D_2O is more efficient than H_2O because D_2O absorbs fewer neutrons. So in a heavy water reactor, the uranium used to make the fuel doesn't have to be enriched. The initial cost of separating the heavy water from light water is offset by the lower cost of the uranium fuel.

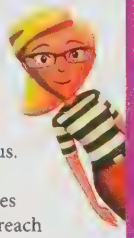
Water passes through a series of extraction towers in which D_2O is separated from H_2O.

H Hydrogen Economy

Hydrogen is a pollution-free fuel. When it burns in air, the only product is water with trace amounts of nitrogen oxides. No carbon dioxide, carbon monoxide, oxides of sulfur, or unburned hydrocarbons are emitted. In a *hydrogen economy*, hydrogen would replace fossil fuels as the energy source for heating, transportation, and industrial processes. Achieving this goal will require new technology for the production, distribution, and storage of hydrogen.

Cars that run on hydrogen are being built. In one model, hydrogen is stored under pressure in a tank. The hydrogen is fed into a fuel cell, where it combines with oxygen to produce electricity. The electricity runs an electric motor that in turn drives the wheels. The valves to the hydrogen tank are designed to shut down if sensors detect a leak.

Large-scale production of hydrogen currently begins with fossil fuels. But in a true hydrogen economy, the source of the hydrogen would not be fossil fuels. Some scientists are working on a process that uses enzymes to extract hydrogen from wood chips or grass. Others are focused on algae that produce hydrogen in the presence of sunlight.



At the Los Angeles auto show in 2008, one auto manufacturer presented this design concept for a hydrogen-powered sports car.

H Hydrogen Peroxide

The strips used to whiten teeth usually contain hydrogen peroxide, H_2O_2. It is a powerful oxidizer that doesn't produce toxic gases or unwanted residues. A 3% aqueous solution is safe for use at home. Stronger concentrations are used to treat wastewater, bleach paper, and make germ-fighting detergents.

Hydrogen peroxide can inhibit the growth of bacteria in water pipes and increase the growth of bacteria that clean up polluted soils. How is this possible? The answer is *selectivity*. Scientists can adjust variables such as pH, temperature, and concentration so that hydrogen peroxide oxidizes one pollutant and not another.

Did You Know?

Hydrogen in the center of the sun has a density of about 200 g/mL. The temperature is about 13 million degrees Celsius. Radiation released when hydrogen nuclei fuse takes about a million years to reach the sun's surface.

H Heavy Water Reactors

Due to the high neutron absorption factor of D_2O over other moderators, heavy water reactors produce larger numbers of radioisotopes than other types of nuclear reactors. Many of these isotopes are used in medicine and agriculture. Heavy water reactors also permit a higher number of uranium-238 atoms to absorb neutrons, which leads to the production of plutonium-239. If a heavy water reactor ran at full power, it could produce 8–10 kg of plutonium per year, which is enough to build a nuclear weapon. But, a large plutonium separation facility would be needed to produce this much weapons-grade plutonium.

H Hydrogen Peroxide

Hydrogen peroxide is a natural metabolite of many organisms, which decompose the H_2O_2 they produce into water and oxygen. Hydrogen peroxide is often used to control odors. It may be applied directly to aqueous wastes containing odorants (such as hydrogen sulfide) or to wet scrubbers that are used to remove pollutants from airstreams. In the case where the odors are the result of biological activity, hydrogen peroxide may be added as a preventive measure to eliminate anoxic (oxygen deficient) conditions, which favor the generation of bad odors.

In 2000, IUPAC published a paper in which *selectivity* was distinguished from *specificity* in relation to analytical tests. A specific test is one that occurs only with the substance of interest. A selective test can occur with multiple substances, but exhibits a degree of preference for the substance of interest. Few tests are specific; many are selective.

H A Hydrogen Economy

Metal hydrides provide a compact way to store hydrogen. Metal hydrides are formed by the reaction of hydrogen with inner transition metals and some transition metals. The smaller hydrogen atoms occupy holes in the crystal lattice of the much larger metal atoms. The reaction takes place under pressure. The stored hydrogen is released through a drop in pressure or an increase in temperature.

The nature of the bonding in metal hydrides isn't well understood. They have the general formula MH_x, where x represents the number of hydrogen atoms in the simplest formula. Because of the variable number of holes in the parent alloy, many metallic hydrides are non-stoichiometric. For example, a titanium hydride has the formula $TiH_{1.7}$.

Transition Metals

Physical Properties

The "sea of electrons" model can explain such properties of transition metals as conductivity and malleability. But it is not adequate to explain the periodic trend in melting points, which reflects an increase in the strength of metallic bonding until Group 6B and a subsequent decrease. To explain this trend, chemists apply molecular orbital bonding theory to metallic bonding; i.e., the existence of bonding and antibonding interactions within a metal.

Sources

An ore must contain enough of the desired metal so that the market value of the metal offsets the cost of finding, removing, and refining the ore. For many metals, the ore must contain at least 30% of the metal. However, with high value metals, such as gold, it may be profitable to mine ore containing a much smaller percentage of the metal.

To Do

Students can use sources such as the business sections of newspapers to research which metals are traded on stock exchanges, and to rank the metals from least expensive to most expensive. Ask students to use what they have learned about different metals to propose reasons for the rankings. (Remind students of how the invention of the Hall-Heroult process affected the value of aluminum.)

Transition Metals

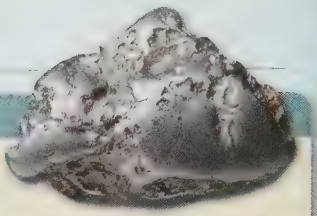
Before 1700

Au gold
Ag silver
Cu copper
Fe iron
Hg mercury
Zn zinc

1700–1799

Co cobalt (1735)
Pt platinum (1735)
Ni nickel (1751†)
Mn manganese (1774)
Mo molybdenum (1778)
W tungsten (1783)
Ti titanium (1791)
Y yttrium (1794)
Cr chromium (1797)

1800–1899

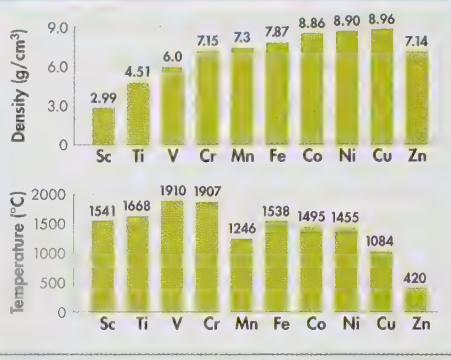


V vanadium (1801)
Nb niobium (1801)
Ta tantalum (1802)
Pd palladium (1803)
Rh rhodium (1803)
Os osmium (1803)
Ir iridium (1803)
Cd cadmium (1817)
Zr zirconium (1824)
Ru ruthenium (1844)
Sc scandium (1878)

After 1900

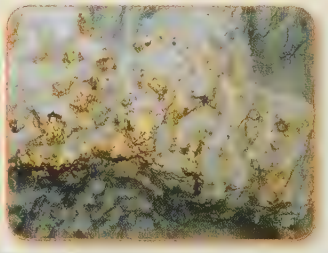
Lu lutetium (1907)
Hf hafnium (1923)
Re rhenium (1925)

Physical Properties



- Most transition metals are ductile, malleable, and good conductors of heat and electric current.
- For transition metals, density tends to increase across a period, while melting point increases to a peak in Group 6B and then decreases.

Except for copper and gold, transition metals, including platinum, have a silvery luster.

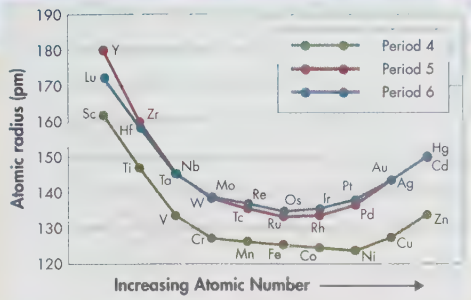


- Compounds of transition metals tend to have color.

Density and Melting Points of Period 4 Transition Metals

Sources

- Transition metals come from mineral deposits in Earth's crust. Minerals that are used for the commercial production of metals are called ores.
- For centuries, people have developed techniques for separating metals from ores. The ore is concentrated and the metal removed by reduction. Then the metal is refined and purified.

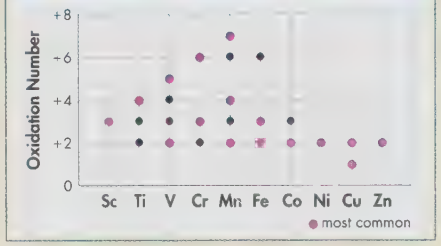


Gold exists as an element in nature. But its ore needs to be concentrated before the gold can be extracted and purified.

R36 Elements Handbook

Atomic Properties

- Among the transition metals, as atomic number increases, there is an increase in the number of electrons in the second-to-highest occupied energy level.
- In periods 5 and 6, transition metals in the same group have identical or almost identical atomic radii. Thus, these pairs of elements have very similar chemical properties. They tend to occur together in nature and are difficult to separate.



Trends in Atomic Size for Transition Metals

Chemical Properties

- There is great variation in reactivity among transition metals. Scandium and yttrium are similar to Group 1A and 2A metals. They are easily oxidized on exposure to air and react with water to release hydrogen. Platinum and gold are extremely unreactive and resist oxidation.
- In general, transition metals have multiple oxidation states. Compounds in which these elements are in their highest oxidation states are powerful oxidizing agents.
- Most transition metals form compounds with distinctive colors. The color of a transition metal compound or solution can indicate the oxidation state of the metal.

Oxidation Numbers of Period 4 Transition Metals

In these aqueous solutions, vanadium, chromium, and manganese are in their highest oxidation states.

The oxidation number of vanadium is +5 in the yellow solution, +4 in the blue solution, +3 in the green solution, and +2 in the purple solution.

Atomic Properties

Metal ions that have a partially filled *d* sublevel are usually colored; metal ions with a completely filled or completely empty *d* sublevel are colorless.

Chemical Properties

The transition metals vary greatly in their reactivity. For example, scandium and yttrium are similar to Group 1A metals in that they are easily oxidized on exposure to air and react with water to produce hydrogen. Yet platinum and gold are extremely unreactive and resist oxidation.

Transition Metals

Cu Copper Alloys

The Bronze Age reigned supreme for many centuries. Because bronze could be cast, it was used for making tools, plowshares, weapons, armor, and decorative objects. About 1200 B.C., there was a disruption of international trade routes and the supply of tin dried up. Metalworkers began to use iron instead of bronze because iron ore was widely available for smelting with charcoal. The substitution of iron for bronze in tools and weapons was the result of iron's abundance rather than any inherent advantages of iron.

Because only 0.13 mm of the Statue of Liberty's copper skin was weathered and oxidized during the statue's first century, the copper skin was one of the few parts of the statue that didn't need to be replaced or rebuilt when the statue was renovated for its centennial. The torch section was the only copper part that required work. It was rebuilt with new copper and patinated before installation to match the rich, green color of the rest of the Statue.

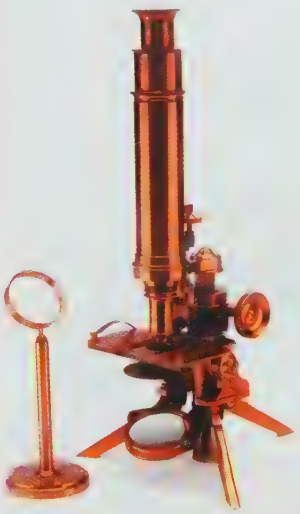
To Do

Encourage students to research the chemistry of patina formation. Have them look at the different compounds that form at various stages and how environmental conditions affect the rate at which a patina forms.

To Do

Beginning in the thirteenth century, some cultures used monumental brasses to commemorate the dead. These large brass plates were engraved with a likeness of the deceased, decorated with heraldic devices and inscriptions, and set on the surface of the tomb. Show students reproductions of rubbings made from plates in the United Kingdom. Compare the rubbings to those made of granite tombstones in New England burial grounds.

Transition Metals



Cu Copper Alloys

Copper was one of the first metals to be widely used. It is found uncombined in nature or easily reduced from its ores. The Roman supply of copper came mainly from Cyprus and was known as *aes Cyprium* (metal of Cyprus). This name evolved to *cyprium* and then *cuprium*, which is why copper has the symbol Cu. Pure copper is valued both for its ability to conduct an electric current and its ability to resist corrosion.

Around 3500 BC, people began to add tin to copper to form bronze. This alloy is harder than pure copper and easier to melt for casting. Metalworkers could produce bronze with different properties by varying the amount of tin. Bronze used to make statues might contain as little as 10% tin by mass. Bronze used to make bells would contain 13% to 25% tin. Most copper coins are bronze with 4% tin and 1% zinc.

When a bronze bell is struck, the clear, loud tone lasts for several seconds. This ancient Chinese bell was probably part of a set of graduated chimes.

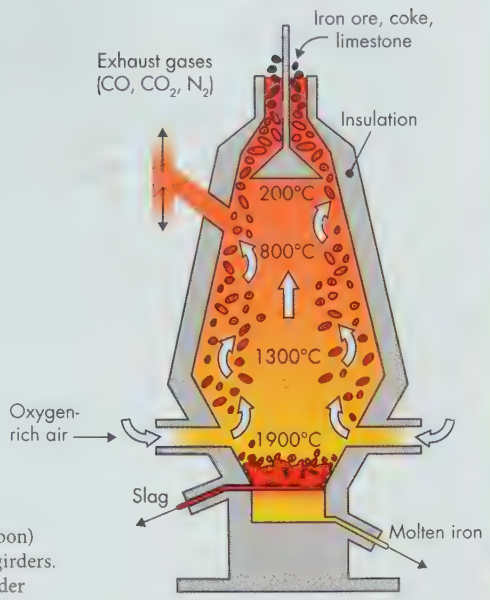
Historically, brass was used to make high-quality scientific instruments like this microscope.

Brass is an alloy of copper and zinc. Brass is harder than pure copper and more malleable than bronze. Brass containing at least 65% copper can be worked when it is cold. Brass with 55% to 65% copper can be worked when it is hot. Before large amounts of gold and silver reached Europe in the 1500s, brass was the metal used for decorative items.

Copper that is exposed to oxygen and water forms a patina of basic copper salts. This thin film protects the underlying metal from further oxidation. The composition of the patina, its color, and the rate at which it forms vary with the climate. The rate is faster near the ocean.

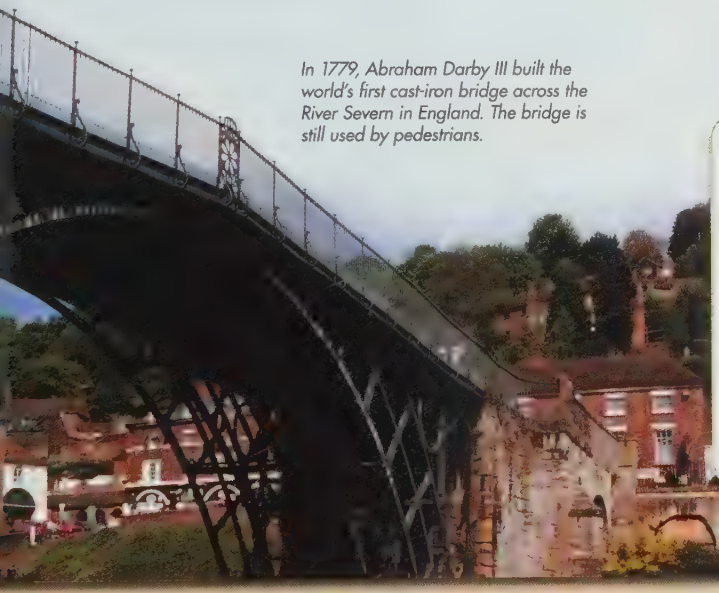
The exterior of this science museum near the harbor in Amsterdam is copper, which has formed a patina.

Fe Iron and Steel



Carbon is used to extract iron from its ores. At first, people used charcoal from burnt wood. In 1709, Abraham Darby invented a process that used coke instead of charcoal. Coke is almost pure carbon. It is produced when coal is heated in the absence of air and the impurities removed as gases. With coke, producing iron became less costly and more efficient.

Iron ore is reduced to metallic iron in a blast furnace. Ore, coke, and limestone are added at the top of the furnace. Molten iron and slag collect at the bottom. The "pig" iron produced contains 3% to 5% carbon and smaller amounts of other impurities, which make the iron brittle. Pig iron can't be rolled or welded, but it can be cast. Cast iron is used to make stoves and engine blocks for cars.



Most pig iron is used to make steel. The methods for making steel differ, but they all lower the carbon content to less than 2% and remove other impurities. About 90% of the steel produced is carbon steel, which contains no other metals. Mild steel, which is malleable and ductile, contains less than 0.2% carbon. Medium steel (0.2% to 0.6% carbon) is used for structural components, such as beams and girders. Because high-carbon steel (0.8% to 1.5% carbon) is harder than other carbon steels, it is used to make items such as drill bits and knives.

Transition metals are used to produce alloy steels with a specific set of properties. The most common stainless steel contains about 18% chromium and 8% nickel.

Blast Furnace

Iron ore typically contains Fe_2O_3, and SiO_2. When heated, limestone produces CaO, which reacts with SiO_2 to form slag. Slag is used to manufacture Portland cement.

In 1779, Abraham Darby III built the world's first cast-iron bridge across the River Severn in England. The bridge is still used by pedestrians.

Did You Know?

Swords made with Damascus steel were highly valued. The source of this quality was the 0.02% **vanadium** in the iron ore that the steel makers used. When they began to use a different source of iron ore, the quality of their steel declined.

Fe Iron and Steel

Various ancient cultures developed techniques for making steel. By 500 B.C., carbon steel was being manufactured in China. There is evidence of ancient forced-draft furnaces on the shores of Lake Victoria, and oral histories indicate that steel was being produced in Africa about 2000 years ago.

In the Bessemer process for making steel, a blast of air is bubbled through molten pig iron in a huge egg-shaped container. The carbon reacts vigorously with the oxygen in the air. With this process, it is not possible to control the final carbon content or the amount of other metals in the alloy.

The open-hearth method uses a shallow lined vessel to produce high quality steel in five to eight hours. The chief advantage of the open-hearth method is that each batch can be analyzed and alloying metals added as needed. When the steel is ready, the furnace is tapped.

In the basic oxygen process, about 300 metric tons of steel can be produced in one hour. The furnace vessel is lined with a basic oxide, such as calcium oxide, and pure oxygen is blown into the molten mass through a narrow tube called a lance at about 10 atmospheres pressure.

Transition Metals

Cd Phytoremediation

Plants used for phytoremediation are called hyperaccumulators because the concentration of a target substance in the plant is greater than its concentration in the soil. One disadvantage of using plants to clean up soil is that the process usually takes longer than the alternatives. One advantage is that the contaminated soil is cleaned up on site. The soil does not have to be dug up and transported to another location for treatment.

Fe Ni Co Permanent Magnets

Currently, neodymium–iron–boron magnets are the most compact magnetic materials available; that is, they exhibit considerable magnetic strength for their density. These magnets are susceptible to corrosion with the main product of surface corrosion being Nd_2O_3. Because the rate of corrosion increases as the temperature increases, the maximum temperature at which the magnets are useful is 120°C. The magnets are often plated with nickel to prevent corrosion.

Au Gold

A gold content of 18k and above is rarely used for jewelry because the high gold content makes the gold alloy soft enough to be easily dented. Various metals are added to gold to form alloys. The most common is copper, which preserves the gold color. Metals such as nickel and zinc are used to produce white gold.

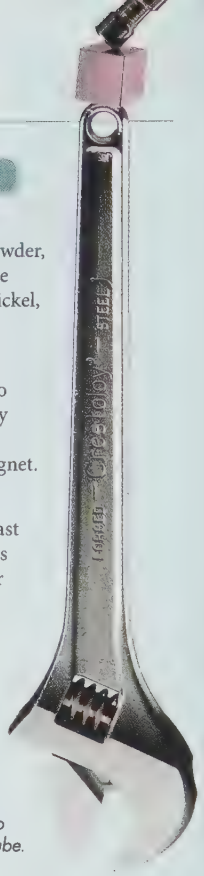
Transition Metals

Cd Phytoremediation

Phytoremediation uses plants such as sunflowers, Indian mustard, and dandelions to remove pollutants from contaminated soil and water. The contaminants include organic solvents, pesticides, and toxic metals such as cadmium and chromium.

Plants have a natural ability to absorb nutrients through their roots. Often a plant does not distinguish a toxic metal such as cadmium from a nutrient such as zinc because these metals have similar chemical properties. So cadmium is absorbed and transported to the leaves and stems, where it accumulates.

The plants are composted or burned after harvesting. The metal residues are buried in an approved landfill or recovered through smelting.



Fe Ni Co Permanent Magnets

Refrigerator magnets contain a barium ferrite, $BaO{\cdot}6Fe_2O_3$, or strontium ferrite, $SrO{\cdot}6Fe_2O_3$, powder, which is embedded in plastic or rubber. Horseshoe magnets usually contain an alloy of aluminum, nickel, and cobalt.

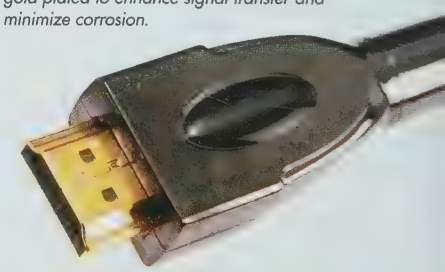
Iron, nickel, and cobalt are strongly attracted to magnetic fields. When these metals are exposed to a magnetic field, their cations line up in an orderly arrangement. When the field is removed, the ions remain lined up, and the material can act as a magnet. This type of magnetism is called ferromagnetism.

A magnet retains its strength unless it is heated past a point called the Curie temperature. For iron, this temperature is 1043 K. For cobalt, it is 1388 K. For nickel, it is 627 K.

Magnets made from a neodymium, boron, and iron alloy are very powerful. If they are allowed to fly together, they will shatter. They are used to check for counterfeit bills because they can detect tiny magnetic particles placed in the ink of genuine bills.

The wrench is strongly attracted to the tiny neodymium-iron-boron cube.

Au Gold



Gold occurs chiefly as small flecks of free metal in veins of quartz. About 5 g of gold is produced from a metric ton (10^6 g) of gold-bearing rock.

Gold can be pounded into sheets so thin that they will transmit light. These sheets, called gold leaf, are used for lettering and decoration in general. Gold is used on the outside surfaces of satellites because it resists corrosion. Its high electrical and thermal conductivity make gold a good choice to plate contacts in microcircuits.

Pure gold is alloyed to make it harder and more durable. Gold alloys are safe to use as fillings for teeth because gold is highly unreactive.

Units called karats (k) are used to describe the purity of gold. Pure gold is 24k or 100% gold. Gold in coins is usually 22k or 92% gold. Gold in rings is often 14k (58% gold).

Connectors in electronics cables may be gold-plated to enhance signal transfer and minimize corrosion.

R40 Elements Handbook

Micronutrients

Trace amounts of some transition metals are essential for human health.

Iron is found mainly in hemoglobin and myoglobin. Hemoglobin is the protein that transports oxygen in blood. Myoglobin is the protein that stores oxygen in muscle tissue. Vitamin C helps the absorption of iron by promoting the reduction of Fe^{3+} ions to Fe^{2+} ions.

Zinc is a cofactor in many enzymes. It helps protect the immune system. Hormones that control growth and reproduction do not function properly without zinc. A lack of zinc impairs the sense of taste and reduces the appetite.

Copper is a component of enzymes that control the synthesis of melanin, hemoglobin, and phospholipids in the sheath that protects nerves.

Molybdenum affects the absorption of copper. It is also needed for the oxidation of lipids and the metabolism of sulfur and nitrogen.

Chromium assists in the metabolism of glucose and may help to control adult-onset diabetes. A lack of chromium may affect growth.

Manganese is required for the proper function of the nervous system and the thyroid gland. It is needed for glucose metabolism. It helps maintain healthy bones and cartilage.

Cobalt is a component of vitamin B_{12}, which is required for the synthesis of red blood cells.

Transition Metal Micronutrients

Element	RDA or AI*	Dietary Sources
Iron	10 mg RDA (M) 20 mg RDA (F)	liver, green vegetables, egg yolk, fish, whole wheat, nuts, oatmeal, molasses, and beans
Zinc	11 mg RDA (M) 8 mg RDA (F)	liver, eggs, meat, milk, whole grains, and shellfish
Copper	900 µg RDA	beans, peas, and shellfish
Molybdenum	45 µg RDA	beans, peas, and whole grains
Chromium	35 µg AI (M) 25 µg AI (F)	meat and whole grains
Manganese	2.3 mg AI (M) 1.8 mg AI (F)	nuts, whole grains, dried fruits, and green leafy vegetables

*Recommended Dietary Allowance or Adequate Intake

Na Sunscreens

You need some exposure to sunlight so your skin cells can make vitamin D, which is needed for healthy bones and teeth. Yet the UV radiation in sunlight can damage skin cells and even lead to skin cancer. The best way to protect your skin is to limit your time in the sun. The next best way is to use a sunscreen.

All the active ingredients in sunscreens protect against UVB light (280–320 nm), which is the primary cause of sunburn. Some ingredients protect against UVA light (320–400 nm), which penetrates deeper and causes long-term damage. A sun protective factor rating (SPF) measures only how effective a sunscreen is against UVB, not UVA.

Titanium dioxide, TiO_2, can reflect and scatter UV light. This stable and nonirritating oxide has one drawback. It looks like white paint on the skin. One manufacturer has addressed this problem by decreasing the size of the TiO_2 particles to a diameter of about 21 nm. At this size, TiO_2 appears transparent because its particles are smaller than wavelengths of visible light and light isn't reflected by the particles.

Did You Know?

An octopus has blood that is blue, not red, because the compound that transports oxygen in an octopus contains **copper**, not iron. Snails, oysters, and spiders are also bluebloods.

Micronutrients

There are probably more than seven transition metal micronutrients. For example, nickel may affect cell membranes in the liver and vanadium may affect growth. Fe^{2+} ions are absorbed in the stomach and small intestine. Vitamin C helps the absorption by promoting the reduction of Fe^{3+} ions to Fe^{2+} ions.

To Do

Students could research the difference between an RDA and an AI; how these quantities are determined; and why the recommended amounts vary by gender.

Na Sunscreens

Skin responds to UV exposure by producing more melanin, which absorbs some of the damaging radiation. But damage can still occur even if a person has naturally dark skin. An active ingredient in sunscreen absorbs, reflects, or scatters radiation in the UV range of 280–400 nm. Examples of organic active ingredients are avobenzene and oxybenzene, which absorb UV light and dissipate the energy as heat. Inorganic products act by reflecting and scattering UV light. Sunscreens containing both organic and inorganic ingredients can have a very high SPF rating.

To Do

Suggest that students compare the active ingredients and ratings for different sunscreens. Have them check to see if the label claims that the product protects against both UVA and UVB radiation.

X = no such compound

R48 Appendix B

Appendix C Safety in the Chemistry Lab

The experiments in this book have been carefully designed to minimize the risk of injury. However, safety is also your responsibility. The following rules are essential for keeping you safe in the laboratory. The rules address pre-lab preparation, proper laboratory practices, and post-lab procedures.

Pre-Lab Preparation

1. Read the entire procedure before you begin. Listen to all of your teacher's instructions. When in doubt about a procedure, ask your teacher.
2. Do only the assigned experiments. Do any experiment only when your teacher is present and has given you permission to work.
3. Know the location and operation of the following safety equipment: fire extinguisher, fire blanket, emergency shower, and eye wash station.
4. Know the location of emergency exits and escape routes. To make it easy to exit quickly, do not block walkways with furniture. Keep your work area orderly and free of personal belongings such as coats and backpacks.
5. Protect your clothing and hair from chemicals and sources of heat. Tie back long hair and roll up loose sleeves when working in the laboratory. Avoid wearing bulky or loose-fitting clothing. Remove dangling jewelry. Wear closed-toe shoes at all times in the laboratory.

Proper Laboratory Practices

6. Even with well-designed and tested laboratory procedures, an accident may occur while you are working in the lab. Report any accident, no matter how minor, to your teacher.
7. Wear chemical splash goggles at all times when working in the laboratory. These goggles are designed to protect your eyes from injury. While working in the lab, do not rub your eyes, because chemicals are easily transferred from your hands to your eyes.

   ⚠ If, despite these precautions, a chemical gets in your eye, remove any contact lenses and immediately wash your eye with a continuous stream of lukewarm water for at least 15 minutes.
8. To reduce danger, waste, and cleanup, always use the minimal amounts of chemicals specified for an experiment.
9. Never taste any chemical used in the laboratory, including food products that are the subject of an investigation. Treat all items as though they are contaminated with unknown chemicals that may be toxic. Keep all food and drink that is not part of an experiment out of the laboratory. Do not eat, drink, or chew gum in the laboratory.

   ⚠ If you accidentally ingest a substance, notify your teacher immediately.
10. Don't use chipped or cracked glassware. Don't handle broken glass. If glassware breaks, tell your teacher and nearby classmates. Discard broken glass as instructed by your teacher.

    ⚠ If, despite these precautions, you receive a minor cut, allow it to bleed for a short time. Wash the injured area under cold, running water and notify your teacher. More serious cuts or puncture wounds require immediate medical attention.
11. Do not handle hot glassware or equipment. You can prevent burns by being aware that hot and cold equipment can look exactly the same.

    ⚠ If you are burned, immediately run cold water over the burned area for several minutes until the pain is reduced. Cooling helps the burn heal. Ask a classmate to notify your teacher.
12. Recognize that the danger of an electrical shock is greater in the presence of water. Keep electrical appliances away from sinks and faucets to minimize the risk of electrical shock. Be careful not to spill water or other liquids in the vicinity of an electrical appliance.

    ⚠ If, despite these precautions, you spill water near an electrical appliance, stand back, notify your teacher, and warn other students in the area.
13. Report any chemical spills immediately to your teacher. Follow your teacher's instructions for cleaning up spills. Warn other students about the identity and location of spilled chemicals.

Safety in the Chemistry Lab **R49**

⚠ If, despite these precautions, a corrosive chemical gets on your skin or clothing, notify your teacher. Then wash the affected area with cold, running water for several minutes.

Post-Lab Procedures

14. Dispose of chemicals in a way that protects you, your classmates, and the environment. Always follow your teacher's directions for cleanup and disposal. Clean your small-scale reaction surface by draining the contents onto a paper towel. Then wipe the surface with a damp paper towel and dry the surface completely. Dispose of the paper towels in the waste bin.

15. Wash your hands thoroughly with soap and water before leaving the laboratory.

A Materials Safety Data Sheet (MSDS) for a chemical describes any safety issues. A diagram summarizes risks related to flammability, health, and reactivity. A number scale indicates the level of risk.

Take appropriate precautions when any of the following safety symbols appears in an experiment.

Safety Symbols

Eye Safety Wear safety goggles.

Clothing Protection Wear a lab coat or apron when using corrosive chemicals or chemicals that can stain clothing.

Skin Protection Wear plastic gloves when using chemicals that can irritate or stain your skin.

Broken Glass Do not use chipped or cracked glassware. Do not heat the bottom of a test tube.

Open Flame Tie back hair and loose clothing. Never reach across a lit burner.

Flammable Substance Do not have a flame near flammable materials.

Corrosive Substance Wear safety goggles, an apron, and gloves when working with corrosive chemicals.

Poison Don't chew gum, drink, or eat in the laboratory. Never taste a chemical in the laboratory.

Fume Avoid inhaling substances that can irritate your respiratory system.

Thermal Burn Do not touch hot glassware or equipment.

Electrical Equipment Keep electrical equipment away from water or other liquids.

Sharp Object To avoid a puncture wound, use scissors or other sharp objects only as intended.

Disposal Dispose of chemicals only as directed.

Hand Washing Wash your hands thoroughly with soap and water.

R50 Appendix C

Appendix D Problem Bank

Chapter 2

1. Are intensive or extensive properties most helpful in identifying a substance? Explain your choice.
2. Classify the following mixtures as homogeneous or heterogeneous.
   a. a toaster
   b. a calculator
   c. the air on a clear day
   d. a copper coin
3. Identify the following as a mixture or a substance.
   a. tomato juice
   b. a rusty, iron fence post
   c. a drop of mercury
   d. a milkshake
4. Classify the following as a physical change or a chemical change.
   a. salad dressing separates into layers after standing
   b. spilled acid burns a hole in cotton jeans
   c. alcohol freezes
   d. ice sublimes
5. Classify the following properties of an aluminum bar as either physical or chemical.
   a. burns in pure oxygen
   b. melts at 660°C
   c. bends easily
   d. is nonmagnetic

Chapter 3

6. How many significant figures are in each measurement?
   a. 786.32 mg
   b. 0.0004 s
   c. 5.060 kg
   d. 7006.0 g
   e. 0.0500 s
   f. 66.066 mg
   g. 4000 m
   h. 40.0×10^3 m
7. Write each of the measurements in Problem 6 in scientific notation.
8. What is the total mass of three gold bars that weigh 5543 mg, 23.45 mg, and 697.4 mg?
9. The normal daily high temperature on the planet Zork is −85°C. Express this temperature in kelvins.
10. Methane, a gas that contributes to global warming, has a density of 0.714 g/L. What is the mass, in grams, of 25.0 L of methane?
11. The density of zinc is 9.394 g/cm^3 at 20°C. What is the volume (in cubic centimeters) of a sphere of zinc metal that has a mass of 15.6 g?
12. Calculate the mass in kilograms of 964 mL of the element mercury. The density of mercury is 13.6 g/mL.
13. Make the following conversions:
   a. 55 mg to grams
   b. 5.76 dL to liters
   c. 0.96 m to micrometers
   d. 5.26 ns to seconds
   e. 87 kg to milligrams
   f. 846 mmol to centimoles
   g. 3.4 nm to picometers
   h. 6.66×10^3 kg to megagrams
   i. 2.34×10^{-5} mL to microliters
14. When you donate a unit of blood to the Red Cross, you "give" about 0.55 L of blood. How many cubic centimeters (cm^3) of blood is this?
15. The recommended daily amount (RDA) of vitamin B_6 for adults is 0.2 cg. How many micrograms of vitamin B_6 should be consumed each day?
16. A person develops jaundice (characterized by yellowing of the skin) when the concentration of bilirubin in his or her blood is 18 mg bilirubin per liter of blood. Assuming a total blood volume of 5.2 L, what is the number of grams of bilirubin in the person's blood?

Appendix D Problem Bank

Answers

Chapter 2

1. Intensive properties: because they depend on the composition of the sample, not the amount of matter in the sample.
2. **a.** heterogeneous **b.** heterogeneous **c.** homogeneous **d.** homogeneous
3. **a.** mixture **b.** mixture **c.** substance **d.** mixture
4. **a.** physical change **b.** chemical change **c.** physical change **d.** physical change
5. **a.** chemical **b.** physical **c.** physical **d.** physical

Chapter 3

6. **a.** 5 **b.** 1 **c.** 4 **d.** 5 **e.** 3 **f.** 5 **g.** 1 **h.** 3
7. **a.** 7.8632×10^2 **b.** 4×10^{-4} **c.** 5.060×10^0 **d.** 7.0060×10^3 **e.** 5.00×10^{-2} **f.** 6.6066×10^1 **g.** 4×10^3 **h.** 4.00×10^4
8. 6264 mg
9. 188 K
10. 17.9 g
11. 1.66 cm^3
12. 13.1 kg
13. **a.** 5.5×10^{-2} g **b.** 5.76×10^{-1} L **c.** 9.6×10^5 µm **d.** 5.26×10^{-9} s **e.** 8.7×10^7 mg **f.** 8.46×10^1 cmol **g.** 3.4×10^3 pm **h.** 6.66 Mg **i.** 2.34×10^{-2} µL
14. 5.5×10^2 cm^3
15. 2×10^3 µg
16. 9.4×10^{-2} g

17. 4.3×10^2 µg

18. 4.26 bottles

19. 2.4×10^5 mg

20. 3.8×10^7 beats/year

21. 2.42 kg

22. 11.6 days

23. **a.** 8.0×10^{-5} cm **b.** 8.0×10^{-1} µm
c. 8.0×10^{-6} dm **d.** 8.0×10^{-4} mm

24. 0.43 s

25. 2.50×10^3 kg

26. 26 m

27. 4 days

28. 3 capsules/dose

29. **a.** 1.03×10^3 packs **b.** 1.41 years

30. **a.** 18.0 g **b.** $31.50

31. 52.8 cm^3 sodium

32. 4.95×10^3 kg

33. 3.93 kg

34. 71.5 kg of air

35. **a.** 1×10^6 cm^3 **b.** 1×10^3 cm^3
c. 5×10^{-21} cm^3 **d.** 2×10^{12} cm^3

Chapter 4

36. **a.** not equal **b.** equal
c. equal **d.** not equal

37. **a.** 23 protons, 23, electrons, 28 neutrons

b. 13 protons, 13 electrons, 14 neutrons

c. 50 protons, 50 electrons, 70 neutrons

d. 72 protons, 72 electrons, 106 neutrons

17. Mites are small eight-legged "bugs" in the same family as spiders. A particularly small mite has a mass of 0.0043 dg. What is the mass of this mite expressed in micrograms?

18. In the United States, a typical can of soda holds 355 mL. How many 2.00-L bottles could be filled from a 24-can case of soda?

19. You are going to carry out a chemical reaction in which you need 16 g of oxygen for every 7.0 g of nitrogen that will be used. If you have 0.554 kg of oxygen, how many milligrams of nitrogen do you need?

20. If your heart beats at an average rate of 72 times per minute, how many times will your heart beat each year?

21. Four empty beakers weigh a total of 1.84 kg. Each beaker when full holds 0.75 kg of water. How much do two full beakers of water weigh?

22. How many days would it take you to count a million pennies if you could count one penny each second? Express the answer to 3 significant figures.

23. A soap bubble film is 8.0×10^2 nm thick. Express this thickness in the following units:

a. centimeters **c.** decimeters
b. micrometers **d.** millimeters

24. The pitcher's mound on a regulation baseball field is 60 feet 6 inches from home plate. How many seconds does it take a 96 mph fastball to reach home plate? (5280 ft = 1 mile)

25. Gemstones such as diamonds are measured in carats, where 1 carat = 2.00 dg. How many kilograms of diamonds were produced if 12.5 million carats of diamonds were mined in a recent year?

26. How many meters does a car moving at 95 km/hour travel in 1.0 second?

27. A milliliter of water is equal to 20 drops of water. If water is dripping from a faucet at the rate of 7 drops per minute, how many days will it take to completely fill a 2.00-L soda bottle?

28. A prescription for a certain drug calls for a dose of 0.200 mg/kg of body weight, four times a day. The drug is packaged in capsules of 5 mg. How many capsules per dose should be given to a patient who weighs 75 kg?

29. A certain low-tar cigarette contains 11.0 mg of tar per cigarette.

a. If all the tar gets into the lungs, how many packs of cigarettes (20 cigarettes per pack) would have to be smoked to produce 0.500 lb of tar? (454 g = 1 lb)

b. If a person smoked two packs per day, how many years would it take to accumulate 0.500 lb of tar?

30. A chemist needs 25.0 mL of a liquid compound.

a. What mass of the compound is necessary if the density is 0.718 g/cm^3?

b. If the compound costs $1.75/gram, what is the cost of this amount of the compound?

31. What volume of sodium has the same mass as 22.0 cm^3 of silicon? The density of sodium is 0.97 g/cm^3; the density of silicon is 2.33 g/cm^3.

32. What is the mass, in kilograms, of a block of platinum that measures 23.0 cm by 78.4 cm by 122 cm? The density of platinum is 22.5 g/cm^3.

33. Sulfuric acid sold for laboratory use consists of 96.7% sulfuric acid, H_2SO_4, by mass. The density of the solution is 1.845 g/cm^3. Compute the number of kilograms of H_2SO_4 in a 2.20-L bottle of laboratory sulfuric acid.

34. How many kilograms of dry air are in a room that measures 15.0 ft by 18.0 ft by 8.00 ft? Use an average density of air of 1.168 g/L. There are 30.48 cm in one foot.

35. Calculate the number of cubic centimeters in each of the following:

a. 1 m^3 **c.** 5 nm^3
b. 1 dm^3 **d.** 2×10^{-3} km^3

Chapter 4

36. In which of these atom(s) is the number of protons equal to the number of neutrons?

a. germanium-72 **c.** silicon-28
b. calcium-40 **d.** hydrogen-1

37. Give the total number of subatomic particles (protons, electrons, and neutrons) in each atom.

a. vanadium-51 **c.** tin-120
b. aluminum-27 **d.** hafnium-178

38. Identify the element name and mass number of an atom with the given composition.

a. 42 protons, 56 neutrons, 42 electrons

b. 2 protons, 1 neutron, 2 electrons

c. 76 protons, 113 neutrons, 76 electrons

d. 31 protons, 40 neutrons, 31 electrons

39. Use the mass and percent abundance of the four isotopes of strontium to calculate the atomic mass of strontium.

Isotope	Mass (amu)	Abundance (%)
Strontium-84	83.193	0.560
Strontium-86	85.909	9.86
Strontium-87	86.908	7.00
Strontium-88	87.906	82.58

40. An atom of carbon and an atom of element Z together weigh 6 amu less than double the weight of an atom of oxygen. If an atom of oxygen weighs 16 amu and an atom of carbon weighs 12 amu, what does an atom of element Z weigh?

Chapter 5

41. What is the maximum number of electrons in each of the following?

a. the fourth energy level

b. the 5*p* energy sublevel

c. a single 4*f* orbital

d. the first three energy levels

42. Write the electron configuration of each atom.

a. nickel

b. sulfur

c. arsenic

d. rubidium

43. Identify the symbols of the elements with the following electron configurations:

a. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^1$

b. $1s^2 2s^2 2p^6 3s^2 3p^5$

c. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 4d^2 5s^2$

d. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6$

44. How many electrons are in the

a. third energy level of an indium atom?

b. second energy level of an oxygen atom?

c. third energy level of a vanadium atom?

d. first energy level of a barium atom?

45. Calculate the wavelength (in meters) of each of these frequencies of electromagnetic radiation.

a. 9.82×10^{19}/s

b. 2.24×10^{14}/s

c. 5.31×10^{7}/s

d. 7.78×10^{10}/s

46. Order the wavelengths in Problem 45 from highest to lowest energy.

Chapter 6

47. Based on their relative positions on the periodic table, which atom in each pair has the smaller atomic radius?

a. Na, K

b. Cl, Br

c. K, Br

d. Ne, Na

48. Based on their relative positions on the periodic table, which atom in each pair has the greater electronegativity?

a. B, C

b. Na, Al

c. Li, Cs

d. As, F

49. Based on their relative positions on the periodic table, which atom in each pair has the highest first ionization energy?

a. F, Br

b. Li, F

c. Ca, Be

d. K, Ar

38. **a.** molybdenum-98 **b.** helium-3 **c.** osmium-189 **d.** gallium-71

39. 87.62 amu

40. 14 amu

Chapter 5

41. **a.** 32 electrons **b.** 6 electrons **c.** 2 electrons **d.** 28 electrons

42 **a.** $1s^2 2s^2 2p^6 3s^2 3p^6 3d^8 4s^2$

b. $1s^2 2s^2 2p^6 3s^2 3p^4$

c. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^3$

d. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 5s^1$

43. **a.** Cu **b.** Cl **c.** Zr **d.** Kr

44. **a.** 18 electrons **b.** 6 electrons **c.** 11 electrons **d.** 2 electrons

45. **a.** 3.05×10^{-12} m **b.** 1.34×10^{-6} m **c.** 5.65 m **d.** 3.85×10^{-3} m

46. highest to lowest: a, b, d, c

Chapter 6

47. **a.** Na **b.** Cl **c.** Br **d.** Ne

48. **a.** C **b.** Al **c.** Li **d.** F

49. **a.** F **b.** F **c.** Be **d.** Ar

50. Element X, group 2A; element Y, group 1A

51. **a.** smaller **b.** smaller
c. larger **d.** larger

Chapter 7

52. The number of valence electrons remains the same.

53. **a.** 2 **b.** 3
c. 3 **d.** 2

54. K^+ and Ca^{2+}

55. MX_2 (M with 2 dots) and MX_3 (M with 3 dots) are valid formulas

56. **a.** 78 **b.** 21
c. 54 **d.** 10

Chapter 8

57. **a.** H:$\ddot{\text{Te}}$:H

b. H:$\ddot{\text{As}}$:H
H

c. Br
Br:$\ddot{\text{Si}}$:Br
Br

d. :$\ddot{\text{I}}$:$\ddot{\text{I}}$:

58. **a.** 10 **b.** 26
c. 26 **d.** 18

59. **a.** bent **b.** pyramidal
c. tetrahedral **d.** linear

60. **a.** polar **b.** polar
c. nonpolar **d.** nonpolar

Chapter 9

61. **a.** molecular **b.** ionic
c. ionic **d.** ionic
e. ionic **f.** molecular
g. molecular **h.** ionic

62. **a.** silicon tetrachloride **b.** PI_3
c. dibromine heptoxide **d.** IF
e. bromine pentafluoride **f.** As_2O_3
g. nitrogen trichloride **h.** P_2O_5

50. Here are the first, second, and third ionization energies (kJ/mol) respectively for the representative elements "X" and "Y."

Element	First ionization energy (kJ/mol)	Second ionization energy (kJ/mol)	Third ionization energy (kJ/mol)
X	738	1450	7732
Y	496	4565	6912

In what group on the periodic table would these elements most likely be found?

51. Would the ion formed from each element be larger or smaller than the atom from which it was formed?
a. calcium
b. aluminum
c. bromine
d. nitrogen

Chapter 7

52. In any group of representative elements on the periodic table, how does the number of valence electrons vary as the elements within the group increase in mass?

53. How many valence electrons are lost by the metallic element when forming each of these ionic compounds?
a. BaS
b. In_2Se_3
c. GaP
d. SrI_2

54. Write the formulas for two cations of representative elements that have the electron configuration $1s^2 2s^2 2p^6 3s^2 3p^6$.

55. If "X" is the formula for any halogen and "M" is the formula for any metal, which of these is a valid formula of an ionic compound formed between "M" and "X"? What is the electron dot structure for "M" in each of the compounds that can be formed?
a. MX_2
b. M_2X_2
c. MX_3
d. M_2X_3

56. How many electrons are in each ion?
a. Pb^{4+} **c.** Te^{2-}
b. Cr^{3+} **d.** C^{4-}

Chapter 8

57. Draw an electron dot structure for each substance.
a. H_2Te
b. AsH_3
c. $SiBr_4$
d. I_2

58. How many electrons are in the electron dot structure for each of these polyatomic ions?
a. cyanide, CN^-
b. bromate ion, BrO_3^-
c. phosphite ion, PO_3^{3-}
d. nitrite, NO_2^-

59. Use VSEPR theory to predict the shape of each molecule in Problem 57.

60. Classify each of the molecules in Problem 57 as polar or nonpolar.

Chapter 9

61. Classify each of these compounds as molecular or ionic.
a. CF_4
b. PtO_2
c. SrI_2
d. NH_4Br
e. K_2CO_3
f. NI_3
g. $C_5H_{10}O_5$
h. $Ba(OH)_2$

62. Name or write the formulas for these molecular compounds.
a. $SiCl_4$
b. phosphorus triiodide
c. Br_2O_7
d. iodine monofluoride
e. BrF_5
f. diarsenic trioxide
g. NCl_3
h. diphosphorus pentoxide

63. Write the formulas for these ionic compounds.

a. barium iodide
b. iron(III) acetate
c. potassium dichromate
d. ammonium bromide
e. cesium nitride
f. cobalt(III) nitrate
g. aluminum oxalate
h. mercurous chloride

64. Name these ionic compounds.

a. Rb_2S
b. LiI
c. $Pb(C_2H_3O_2)_2$
d. Mg_3N_2
e. $HgCl_2$
f. $CuClO_3$
g. NaCN
h. $Cr(ClO_4)_3$

65. Name these compounds.

a. Cs_2O
b. SnS_2
c. N_4S_4
d. B_2O_3
e. H_2CrO_4
f. CaC_2O_4
g. $(NH_4)_3PO_4$
h. As_4O_{10}

66. Write the formulas for these compounds.

a. calcium oxide
b. sulfurous acid
c. diboron tetrachloride
d. calcium hydrogen phosphate
e. tin(II) chromate
f. ferric hydroxide
g. manganese(II) chlorite
h. iodine monochloride

67. Explain why it is not fair to be asked to write a formula for each named "compound."

a. iron bromide
b. sulfur oxide
c. lead hypochlorite
d. phosphorus chloride

68. Iron forms two compounds with oxygen. One compound consists of 1.396 g of iron and 0.400 grams of oxygen. The other has 0.582 g iron and 0.250 g oxygen. Show by calculation whether this pair of compounds obeys the law of multiple proportions.

Chapter 10

69. How many of each kind of atom are in a formula unit of each compound?

a. $(NH_4)_2SO_3$
b. $AlPO_4$
c. $Ca(C_2H_3O_2)_2$
d. $Fe_2(SO_4)_3$

70. How many of each kind of atom are in a molecule of each compound?

a. $C_3H_7O_2$
b. $C_3H_5(OH)_3$
c. $C_2H_4(COOH)_2$
d. $C_7H_5(NO_3)_3$

71. Calculate the molar mass of each of these binary ionic compounds.

a. MgO
b. $AlCl_3$
c. Hg_2I_2
d. Sr_3N_2

72. Calculate the molar mass of each of these ionic compounds.

a. $(NH_4)_2C_2O_4$
b. $Ca(OH)_2$
c. Na_2HPO_4
d. $Mg(HSO_4)_2$

73. Calculate the molar mass of each of these molecular compounds.

a. N_2O_5
b. C_3H_7OH
c. SO_3
d. XeF_6

74. Calculate the molar mass of each of these compounds.

a. DEET, $C_{12}H_{17}ON$, an insect repellent
b. aspartame, $C_{14}H_{18}N_2O_5$, a sugar substitute
c. codeine, $C_{18}H_{21}NO_3$, an analgesic (painkiller)
d. sodium benzoate, $NaC_7H_5O_2$, a food preservative

75. What is the mass, in grams, of each of the following?

a. 5.000 mol Ar
b. 1.64 mol $NaNO_2$
c. 0.886 mol $(NH_4)_2SO_4$
d. 18.3 mol SiF_4

63. a. BaI_2 b. $Fe(C_2H_3O_2)_3$ c. $K_2Cr_2O_7$ d. NH_4Br e. Cs_3N f. $Co(NO_3)_3$ g. $Al_2(C_2O_4)_3$ h. Hg_2Cl_2

64. a. rubidium sulfide b. lithium iodide c. lead(II) acetate d. magnesium nitride e. mercury(II) chloride f. copper(I) chlorate g. sodium cyanide h. chromium(III) perchlorate

65. a. cesium oxide b. tin(II) sulfide c. tetranitrogen tetrasulfide d. diboron trioxide e. chromic acid f. calcium oxalate g. ammonium phosphate h. tetraarsenic decoxide

66. a. CaO b. H_2SO_3 c. B_2Cl_4 d. $CaHPO_4$ e. $SnCrO_4$ f. $Fe(OH)_3$ g. $Mn(ClO_2)_2$ h. ICl

67. a. The ionic charge of iron must be given by a Roman numeral.

b. Prefixes must be used in the name of a molecular compound.

c. The ionic charge of lead must be given by a Roman numeral.

d. Prefixes must be used in the name of a molecular compound.

68. The ratio of masses of iron per gram of oxygen is 3:2, so these compounds obey the law of multiple proportions.

Chapter 10

69. a. N, 2; H, 8; S, 1; O, 3 b. Al, 1; P, 1; O, 4 c. Ca, 1; C, 4; H, 6; O, 4 d. Fe, 2; S, 3; O, 12

70. a. C, 3; H, 7; O, 2 b. C, 3; H, 8; O, 3 c. C, 4; H, 6; O, 4 d. C, 7; H, 5; N, 3; O, 9

71. a. 40.3 g b. 133.5 g c. 655.0 g d. 217.2 g

72. a. 124.0 g b. 74.1 g c. 142.0 g d. 218.5

73. a. 108.0 g b. 60.0 g c. 80.1 g d. 245.3 g

74. a. 191.0 g b. 294.0 g c. 299.0 g d. 144.0 g

75. a. 199.5 g b. 113 g c. 117 g d. 1.91×10^3 g

76. **a.** 2.97 mol **b.** 9.26×10^{-4} mol
c. 0.692 mol **d.** 29.5 mol

77. **a.** 2.65×10^{24} molecules
b. 1.71×10^{23} formula units
c. 9.75×10^{23} molecules
d. 7.71×10^{24} formula units

78. **a.** 0.121 mol **b.** 2.46 mol
c. 0.664 mol **d.** 15.0 mol

79. **a.** 81.5 L **b.** 1.45 L
c. 189 L **d.** 28.2 L

80. **a.** 2.52 mol **b.** 0.341 mol
c. 3.96×10^{-2} mol **d.** 5.63 mol

81. **a.** 2.00×10^{23} molecules
b. 2.16×10^{23} atoms
c. 6.84×10^{21} formula units
d. 2.37×10^{23} formula units

82. **a.** 1.86×10^{-12} g **b.** 6.43 g
c. 55 g **d.** 1.33×10^{-2} g

83. **a.** 3.49 g **b.** 555 g
c. 279 g **d.** 5.7×10^{-3} g

84. **a.** 0.148 L **b.** 33.5 L
c. 0.813 L **d.** 54.9 L

85. **a.** 1.72×10^{24} molecules
b. 9.03×10^{22} molecules
c. 1.28×10^{27} molecules
d. 1.85×10^{21} atoms

86. **a.** 0.136 L **b.** 2.27 L
c. 432 L **d.** 167 L

87. **a.** 63 oxygen atoms
b. 3.61×10^{24} oxygen atoms
c. 1.08×10^{23} oxygen atoms
d. 1.82×10^{23} oxygen atoms

88. **a.** 23 g **b.** 2.50 g
c. 222 g **d.** 7.72 g

89. **a.** 86.6% Pb, 13.4% O
b. 62.1% C, 10.3% H, 27.6% O
c. 18.3% K, 59.3% I, 22.4% O
d. 29.1% Na, 40.6% S, 30.3% O
e. 57.2% I, 42.8% F
f. 0.69% H, 55.1% Br, 44.2% O
g. 56.4% P, 43.6% O
h. 54.5%C, 9.1% H, 36.4 % C

76. How many moles is each of the following?
a. 579 g Pt
b. 0.0426 g NO_2
c. 56.8 g H_2SO_3
d. 6.78×10^3 g CsH_2PO_4

77. Find the number of representative particles in each of the following:
a. 4.40 mol Pd
b. 0.284 mol NaI
c. 1.62 mol NH_3
d. 12.8 mol $Fe(C_2H_3O_2)_2$

78. How many moles is each of the following?
a. 7.26×10^{22} atoms Zr
b. 1.48×10^{24} molecules C_2H_6O
c. 4.00×10^{23} formula units $KClO_3$
d. 9.02×10^{24} molecules OF_2

79. Calculate the volume, in liters, of each of these gases at STP.
a. 3.64 mol H_2
b. 0.0648 mol C_2H_6
c. 8.44 mol SO_3
d. 1.26 mol Xe

80. How many moles is each of the following at STP?
a. 56.4 L He
b. 7.64 L N_2
c. 0.888 L CO
d. 126 L SO_2

81. Calculate the number of representative particles in each mass.
a. 14.6 g CO_2
b. 68.3 g Os
c. 0.847 g KCl
d. 174 g Au_2O_3

82. Calculate the mass of each of the following samples.
a. 7.00×10^9 molecules Br_2
b. 9.22×10^{22} formula units NaF
c. 4.8×10^{24} atoms Li
d. 2.66×10^{20} molecules H_2CO

83. Find the mass of each of the gases at STP.
a. 2.44 L O_2 **c.** 78.0 L SO_3
b. 777 L CH_4 **d.** 0.0642 L H_2

84. Calculate the volume of each of these gases at STP.
a. 0.469 g Cl_2
b. 44.8 g NO
c. 2.76 g N_2O_3
d. 93.2 g F_2

85. Calculate the number of representative particles in each volume.
a. 64.0 L H_2S
b. 3.36 L C_3H_8
c. 4.78×10^4 L HF
d. 6.88×10^{-2} L Kr

86. Find the volume at STP of the following:
a. 3.66×10^{21} molecules F_2
b. 6.11×10^{22} molecules PH_3
c. 1.16×10^{25} atoms Ne
d. 4.48×10^{24} molecules C_2H_2

87. Calculate the number of oxygen atoms in each of the following:
a. 7 molecules of the explosive nitroglycerine, $C_3H_5(NO_3)_3$
b. 3.00 mol of the antiseptic hydrogen peroxide, H_2O_2
c. a balloon filled with 2.00 L O_2
d. 8.04 g of the fertilizer, NH_4NO_3

88. Calculate the number of grams of hydrogen in each of the following.
a. a balloon filled with 7.06×10^{24} hydrogen molecules
b. a balloon filled with 14.0 L of methane, CH_4, at STP
c. a 2.00-L bottle of water (density of H_2O = 1.00 g/mL)
d. a 69.5-g ice cube (density of ice = 0.917 g/cm^3)

89. Calculate the percent composition of each compound.
a. PbO_2
b. $(CH_3)_2CO$
c. KIO_3
d. $Na_2S_2O_3$
e. IF_5
f. $HBrO_4$
g. P_4O_6
h. C_3H_7COOH

90. Use the answers from Problem 89 to calculate the number of grams of the indicated element in the compound.

a. lead in 63.8 g PbO_2

b. carbon in 1.664 g $(CH_3)_2CO$

c. oxygen in 36.8 g KIO_3

d. sulfur in 6.26 g $Na_2S_2O_3$

e. fluorine in 594 g IF_5

f. bromine in 82.7 g $HBrO_4$

g. phosphorus in 2.66 g P_4O_6

h. carbon in 55.0 g C_3H_7COOH

91. Which of these are empirical formulas?

a. $Al_2(SO_4)_3$

b. $C_6H_4Cl_2$

c. $C_2H_4(OH)_2$

d. $K_2Cr_2O_7$

92. What is the empirical formula of

a. $C_6H_{16}N_2$, a compound used to make nylon?

b. $C_6H_8N_2$, a component of chocolate?

c. C_8H_8, used to make polystyrene foam plastics?

d. C_3H_7OH, rubbing alcohol?

93. Determine the empirical formula for each compound from the percent composition data.

a. 85.71% C, 14.29% H

b. 60.94% Ba, 10.65% C, 28.41% O

c. 37.50% C, 12.50% H, 50.00% O

d. 27.87% P, 72.13% S

e. 67.61% U, 32.39% F

f. 74.19% Na, 25.79% O

g. 32.43% C, 5.41% H, 43.24% O, 18.92% N

h. 18.70% Li, 16.26% C, 65.04% O

94. Find the molecular formula from the given empirical formula and molar mass.

Empirical formula	Molar mass (g/mol)	Molecular formula
C_2H_3	54.0	a. _____
C_2H_2Cl	123.0	b. _____
$C_3H_4O_3$	176.0	c. _____
C_5H_7N	162.0	d. _____

95. A compound with a molar mass of 312.2 g/mol contains 69.23% C, 3.85% H, and 26.92% N. What is the molecular formula of this compound?

96. The molar mass of caffeine, the stimulant found in coffee, is 194.0 g/mol. The percent composition of caffeine is 49.48% C, 5.19% H, 28.85% N, and 16.48% O. What is the molecular formula of caffeine?

97. Linoleic acid, which has a molar mass of 280.0 g/mol, is found in many vegetable oils. The percent composition of this compound is 77.1% carbon, 11.4% hydrogen, and 11.4% oxygen. Find the empirical formula and molecular formula of this compound.

98. A 2.716-g sample of a compound of C, H, N, and O was found to contain 0.7580 g C, 0.0633 g H, and 0.8843 g N. The molar mass of the compound is 129 g/mol. Calculate the compound's empirical and molecular formula.

Chapter 11

99. What is the function of the element platinum in this reaction?

$$2H_2 + O_2 \xrightarrow{Pt} 2H_2O$$

100. Balance the following equations:

a. $Hg(NO_3)_2 + NH_4SCN \longrightarrow Hg(SCN)_2 + NH_4NO_3$

b. $CH_4O + O_2 \longrightarrow CO_2 + H_2O$

c. $Ca + Cl_2 \longrightarrow CaCl_2$

d. $Na_3PO_4 + CoCl_2 \longrightarrow Co_3(PO_4)_2 + NaCl$

e. $Fe + AgNO_3 \longrightarrow Fe(NO_3)_2 + Ag$

f. $N_2H_4 \longrightarrow NH_3 + N_2$

g. $C_{12}H_{26} + O_2 \longrightarrow CO_2 + H_2O$

h. $CuCl + Mg \longrightarrow Cu + MgCl_2$

101. Classify each of the equations in Problem 100 by type.

102. Write balanced equations for each of these reactions. Indicate states of matter in your equations.

a. Potassium metal reacts with water to form hydrogen gas and aqueous potassium hydroxide.

b. Nitrogen monoxide gas reacts with gaseous carbon monoxide to form carbon dioxide gas and nitrogen gas.

90. **a.** 55.3 g Pb **b.** 1.03 g C
c. 8.24 g O **d.** 2.54 g S
e. 254 g F **f.** 45.6 g Br
g. 1.50 g P **h.** 30.0 g C

91. **a.** yes **b.** no
c. no **d.** yes

92. **a.** C_3H_8N **b.** C_3H_4N
c. CH **d.** C_3H_7OH

93. **a.** CH_2 **b.** BaC_2O_4
c. CH_4O **d.** P_2S_5
e. UF_6 **f.** Na_2O
g. $C_2H_4O_2N$ **h.** Li_2CO_3

94. **a.** C_4H_6 **b.** $C_4H_4Cl_2$
c. $C_6H_8O_6$ **d.** $C_{10}H_{14}N_2$

95. $C_{18}H_{12}N_6$

96. $C_8H_{10}N_4O_2$

97. empirical formula, $C_9H_{16}O$; molecular formula, $C_{18}H_{32}O_2$

98. empirical formula, CHNO; molecular formula, $C_3H_3N_3O_3$

Chapter 11

99. acting as a catalyst

100. **a.** $Hg(NO_3)_2 + 2NH_4SCN \rightarrow Hg(SCN)_2 + 2NH_4NO_3$

b. $2CH_4O + 3O_2 \rightarrow 2CO_2 + 4H_2O$

c. $Ca + Cl_2 \rightarrow CaCl_2$

d. $2Na_3PO_4 + 3CoCl_2 \rightarrow Co_3(PO_4)_2 + 6NaCl$

e. $Fe + 2AgNO_3 \rightarrow Fe(NO_3)_2 + 2Ag$

f. $3N_2H_4 \rightarrow 4NH_3 + N_2$

g. $2C_{12}H_{26} + 37O_2 \rightarrow 24CO_2 + 26H_2O$

h. $2CuCl + Mg \rightarrow 2Cu + MgCl_2$

101. **a.** double-replacement **b.** combustion
c. combination **d.** double-replacement
e. single-replacement **f.** decomposition
g. combustion **h.** single replacement

102. **a.** $2K(s) + 2H_2O(l) \rightarrow H_2(g) + 2KOH(aq)$

b. $2NO(g) + 2CO(g) \rightarrow 2CO_2(g) + N_2(g)$

c. $4HCl(aq) + O_2(g) \rightarrow 2H_2O(l) + 2Cl_2(g)$

d. $Ca(OH)_2(aq) + 2HC_2H_3O_2(aq) \rightarrow 2H_2O(l) + Ca(C_2H_3O_2)_2(aq)$

e. $3O_2(g) + 2PbS(s) \rightarrow 2SO_2(g) + 2PbO(s)$

f. $Li_2O(s) + H_2O(l) \rightarrow 2LiOH(aq)$

g. $MnO_2(s) + H_2C_2O_4(aq) \rightarrow MnO(s) + H_2O(l) + 2CO_2(g)$

h. $B_2H_6(g) + 3O_2(g) \rightarrow 3H_2O(l) + B_2O_3(s)$

103. a. $2HCl(aq) \xrightarrow{electricity} H_2(g) + Cl_2(g)$

b. $3Br_2(l) + 2AlI_3(aq) \rightarrow 2AlBr_3(aq) + 3I_2(aq)$

c. $2Na(s) + S(s) \rightarrow Na_2S(s)$

d. $Ba(OH)_2(aq) + 2HNO_3(aq) \rightarrow 2H_2O(l) + Ba(NO_3)_2(aq)$

e. $2C_7H_{14}O_2(l) + 19O_2(g) \rightarrow 14H_2O(l) + 14CO_2(g)$

f. $Ni(NO_3)_2(aq) + Na_2CO_3(aq) \rightarrow NiCO_3(s) + 2NaNO_3(aq)$

104. a. $MnO_2 + 4HCl \rightarrow MnCl_2 + Cl_2 + 2H_2O$

b. $PCl_5 + 4H_2O \rightarrow H_3PO_4 + 5HCl$

c. $Ca_3P_2 + 6H_2O \rightarrow 2PH_3 + 3Ca(OH)_2$

d. $Li_3N + 3H_2O \rightarrow 3LiOH + NH_3$

e. $2H_2O_2 + N_2H_4 \rightarrow N_2 + 4H_2O$

f. $SiCl_4 + 2Mg \rightarrow 2MgCl_2 + Si$

g. $V_2O_5 + 2H_2 \rightarrow V_2O_3 + 2H_2O$

h. $HBr + KHSO_3 \rightarrow KBr + H_2O + SO_2$

105. a. $BaSO_4$ **b.** $CrCO_3$
c. no precipitate formed **d.** HgS

106. a. $3Ni^{2+}(aq) + 6Cl^-(aq) + 6K^+(aq) + 2PO_4^{3-}(aq) \rightarrow Ni_3(PO_4)_2(s) + 6Cl^-(aq) + 6K^+(aq)$

b. $2H^+(aq) + 2C_2H_3O_2^-(aq) + Ca^{2+}(aq) + 2OH^-(aq) \rightarrow 2H_2O(l) + Ca^{2+}(aq) + 2C_2H_3O_2^-(aq)$

c. $Ca^{2+}(aq) + 2I^-(aq) + 2Na^+(aq) + SO_4^{2-}(aq) \rightarrow CaSO_4(s) + 2I^-(aq) + 2Na^+(aq)$

d. $2Na^+(aq) + 2OH^-(aq) + Pb^{2+}(aq) + 2NO_3^-(aq) \rightarrow Pb(OH)_2(s) + 2Na^+(aq) + 2NO_3^-(aq)$

107. a. $Cl^-(aq) + K^+(aq)$ **b.** $Ca^{2+}(aq) + C_2H_3O_2^-(aq)$
c. $I^-(aq) + Na^+(aq)$ **d.** $Na^+(aq) + NO_3^-(aq)$

108. a. $3Ni^{2+}(aq) + 2PO_4^{3-}(aq) \rightarrow Ni_3(PO_4)_2(s)$

b. $2H^+(aq) + 2OH^-(aq) \rightarrow 2H_2O(l)$

c. $Ca^{2+}(aq) + SO_4^{2-}(aq) \rightarrow CaSO_4(s)$

d. $Pb^{2+}(aq) + 2OH^-(aq) \rightarrow Pb(OH)_2(s)$

c. Hydrochloric acid reacts with oxygen gas to form liquid water and chlorine gas.

d. Aqueous calcium hydroxide reacts with acetic acid to form water and aqueous calcium acetate.

e. Oxygen gas reacts with solid lead(II) sulfide to form sulfur dioxide gas and lead(II) oxide.

f. Solid lithium oxide reacts with water to form aqueous lithium hydroxide.

g. Solid manganese dioxide reacts with oxalic acid to form solid manganese(II) oxide, water, and gaseous carbon dioxide.

h. Gaseous diboron hexahydride reacts with oxygen gas to form liquid water and solid diboron trioxide.

103. Complete and then balance each of these equations.

a. $HCl(aq) \xrightarrow{electricity}$

b. $Br_2(l) + AlI_3(aq) \longrightarrow$

c. $Na(s) + S(s) \longrightarrow$

d. $Ba(OH)_2(aq) + HNO_3(aq) \longrightarrow$

e. $C_7H_{14}O_2(l) + O_2(g) \longrightarrow$

f. $Ni(NO_3)_2(aq) + Na_2CO_3(aq) \longrightarrow$

104. Balance each of these equations.

a. $MnO_2 + HCl \longrightarrow MnCl_2 + Cl_2 + H_2O$

b. $PCl_5 + H_2O \longrightarrow H_3PO_4 + HCl$

c. $Ca_3P_2 + H_2O \longrightarrow PH_3 + Ca(OH)_2$

d. $Li_3N + H_2O \longrightarrow LiOH + NH_3$

e. $H_2O_2 + N_2H_4 \longrightarrow N_2 + H_2O$

f. $SiCl_4 + Mg \longrightarrow MgCl_2 + Si$

g. $V_2O_5 + H_2 \longrightarrow V_2O_3 + H_2O$

h. $HBr + KHSO_3 \longrightarrow KBr + H_2O + SO_2$

105. Use Table 11.3 to predict whether a precipitate will form when aqueous solutions of these pairs of salts are mixed. If a precipitate forms, write its formula.

a. ammonium sulfate and barium bromide

b. chromium(II) chloride and lithium carbonate

c. potassium nitrate and sodium chloride

d. sodium sulfide and mercury(II) nitrate

106. Write a balanced complete ionic equation for each of these double-replacement reactions. All the reactants are in aqueous solution.

a. nickel(II) chloride + potassium phosphate

b. acetic acid + calcium hydroxide

c. calcium iodide + sodium sulfate

d. sodium hydroxide + lead(II) nitrate

107. Identify the spectator ions in each of the reactions in Problem 106.

108. Write net ionic equations for each of the reactions in Problem 106.

Chapter 12

109. Interpret each equation in terms of interacting particles.

a. $H_2 + F_2 \longrightarrow 2HF$

b. $2K_3PO_4 + 3CoCl_2 \longrightarrow Co_3(PO_4)_2 + 6KCl$

c. $2PbS + 3O_2 \longrightarrow 2PbO + 2SO_2$

d. $Fe + S \longrightarrow FeS$

110. Write all possible mole ratios for these equations.

a. $2NO + Cl_2 \longrightarrow 2NOCl$

b. $2KClO_3 \longrightarrow 2KCl + 3O_2$

c. $3N_2H_4 \longrightarrow 4NH_3 + N_2$

d. $2Na + O_2 \longrightarrow Na_2O_2$

111. Show by calculation that the following equations obey the law of conservation of mass:

a. $3NO_2 + H_2O \longrightarrow 2HNO_3 + NO$

b. $4HCl + O_2 \longrightarrow 2H_2O + 2Cl_2$

c. $2Li + S \longrightarrow Li_2S$

d. $2CH_4O + 3O_2 \longrightarrow 2CO_2 + 4H_2O$

112. Nitric acid, HNO_3, is produced by a process that allows nitrogen dioxide to react with water.

$3NO_2(g) + H_2O(l) \longrightarrow 2HNO_3(aq) + NO(g)$

a. How many moles of nitrogen dioxide, NO_2, are required to produce 3.56 mol of nitric acid?

b. How many moles of water react with 0.946 mol of nitrogen dioxide?

113. Calcium hydroxide reacts with nitric acid to produce an aqueous solution of calcium nitrate.

$$Ca(OH)_2(aq) + 2HNO_3(aq) \longrightarrow 2H_2O(l) + Ca(NO_3)_2(aq)$$

a. How many moles of calcium hydroxide are needed to react with 5.88 mol of nitric acid?

b. How many moles of calcium nitrate are produced when 2.30 mol of water are made in this reaction?

114. Chromium combines with oxygen to form chromium(III) oxide.

$$4Cr(s) + 3O_2(g) \longrightarrow 2Cr_2O_3(s)$$

a. How many moles of chromium are needed to react with 45.6 g of oxygen?

b. How many moles of chromium(III) oxide are produced when 2.86 g of chromium react?

115. Sodium hydroxide is formed when sodium oxide reacts with water.

$$Na_2O(s) + H_2O(l) \longrightarrow 2NaOH(aq)$$

a. Calculate the grams of sodium hydroxide formed when 2.24 moles of sodium oxide react with water.

b. What mass of water (in centigrams) is needed to react with 0.126 mol of sodium oxide?

116. The reaction of nitrogen monoxide with carbon monoxide produces carbon dioxide and nitrogen.

$$2NO(g) + 2CO(g) \longrightarrow 2CO_2(g) + N_2(g)$$

a. How many liters of nitrogen monoxide at STP are needed to produce 3.40 mol of nitrogen gas?

b. When 2.18 moles of nitrogen are made in this reaction, how many liters of carbon dioxide at STP are produced?

117. Hydrogen fluoride gas is produced directly from its component elements.

$$H_2(g) + F_2(g) \longrightarrow 2HF(g)$$

a. When 40.0 L of fluorine at STP reacts with an excess of hydrogen, how many moles of hydrogen fluoride are made?

b. How many moles of fluorine are needed to make 8.04 L of hydrogen fluoride at STP?

118. Rust (iron(III) oxide) is formed by the reaction of oxygen with iron.

$$4Fe(s) + 3O_2(g) \longrightarrow 2Fe_2O_3(s)$$

a. Calculate the mass of oxygen required to react with 10.0 g of iron.

b. How many grams of rust form when 2.48 g of iron reacts with an excess of oxygen?

119. Silver chloride precipitates when aqueous solutions of calcium chloride and silver nitrate are mixed.

$$CaCl_2(aq) + 2AgNO_3(aq) \longrightarrow 2AgCl(s) + Ca(NO_3)_2(aq)$$

a. How many grams of calcium nitrate are formed when 0.500 g of calcium chloride reacts with an excess of silver nitrate?

b. How many grams of calcium chloride are required to react completely with 34.8 g of silver nitrate?

120. The complete combustion of octane, a component of gasoline, forms carbon dioxide and water.

$$2C_8H_{18}(l) + 25O_2(g) \longrightarrow 16CO_2(g) + 18H_2O(l)$$

a. How many grams of C_8H_{18} must be reacted to give 5.00 g of CO_2?

b. How many liters of oxygen gas at STP are required to burn 2.20 g C_8H_{18}?

121. A precipitate of nickel(II) carbonate forms when aqueous solutions of sodium carbonate and nickel(II) nitrate are mixed.

$$Ni(NO_3)_2(aq) + Na_2CO_3(aq) \longrightarrow NiCO_3(s) + 2NaNO_3(aq)$$

a. How many grams of each reactant must be used to form 67.2 g of the precipitate?

b. When 1.88 g of nickel(II) carbonate are formed, how many grams of sodium nitrate are produced?

122. One way to make ethanol is to react ethene with water at high pressure.

$$C_2H_4(g) + H_2O(g) \longrightarrow C_2H_6O(l)$$

a. How many grams of each reactant are needed to produce 8.84 g of ethanol?

b. How many liters of ethanol are produced when 1.00 kg of ethene is reacted with an excess of water? The density of ethanol is 0.789 g/mL.

Chapter 12

109. a. One molecule of hydrogen reacts with one molecule of fluorine to form two molecules of hydrogen fluoride.

b. Two formula units of potassium phosphate react with three formula units of cobalt(II) chloride to form one formula unit of cobalt(II) phosphate and six formula units of potassium chloride.

c. Two formula units of lead(II) sulfide react with three molecules of oxygen to form two formula units of lead(II) oxide and two molecules of sulfur dioxide.

d. One atom of iron reacts with one atom of sulfur to form one formula unit of iron(II) sulfide.

110. a. 2 mol NO/1 mole Cl_2, 2 mol NO/2 mol NOCl. 1 mol Cl_2/2 mol NO, 1 mol Cl_2/2 mol NOCl, 2 mol NOCl/2 mol NO, 2 mol NOCl/1 mol Cl_2

b. 2 mol $KClO_3$/2 mol KCl, 2 mol $KClO_3$/3 mol O_2, 2 mol KCl/2 mol $KClO_3$, 2 mol KCl/3 mol O_2, 3 mol O_2/2 mol KCl, 3 mol O_2/2 mol $KClO_3$

c. 3 mol N_2H_4/4 mol NH_3, 3 mol N_2H_4/1 mol N_2, 4 mol NH_3/3 mol N_2H_4, 4 mol NH_3/1 mol N_2, 1 mol N_2/3 mol N_2H_4, 1 mol N_2/4 mol NH_3

d. 2 mol Na/1 mol O_2, 2 mol Na/1 mol Na_2O_2, 1 mol O_2/2 mol Na, 1 mol O_2/1 mol Na_2O_2, 1 mol Na_2O_2/1 mol O_2, 1 mol Na_2O_2/2 mol Na

111. a. 138.0 g + 18.0 g = 126.0 g + 30.0 g
156.0 g = 156.0 g

b. 146.0 g + 32.0 g = 36.0 g + 142.0 g
178.0 g = 178.0 g

c. 13.8 g + 32.1 g = 45.9 g
45.9 g = 45.9 g

d. 64.0 g + 96.0 g = 88.0 g + 72.0 g
160.0 g = 160.0 g

112. a. 5.34 mol NO_2 **b.** 0.315 mol H_2O

113. a. 2.94 mol $Ca(OH)_2$ **b.** 1.15 mol $Ca(NO_3)_2$

114. a. 1.90 mol Cr **b.** 0.0275 mol Cr_2O_3

115. a. 179 g NaOH **b.** 227 cg H_2O

116. a. 152 L NO **b.** 97.7 L CO_2

117. a. 3.57 mol HF **b.** 0.179 mol F_2

118. a. 4.30 g O_2 **b.** 3.55 g Fe_2O_3

119. a. 0.739 g $Ca(NO_3)_2$ **b.** 11.4 g $CaCl_2$

120. a. 1.62 g C_8H_{18} **b.** 5.40 L O_2

121. a. 103 g $Ni(NO_3)_2$ and 60.0 g Na_2CO_3

b. 2.69 g $NaNO_3$

122. a. 5.38 g C_2H_4, 3.46 g H_2O

b. 2.08 L C_2H_6O

123. $Al_2(SO_4)_3(aq) + 6NaOH(aq) \rightarrow 2Al(OH)_3(s) + 3Na_2SO_4(aq)$

a. 4.36 g NaOH **b.** 20.8 g $Al(OH)_3$

124. a. 10.6 g H_2O_2 **b.** 5.53 L O_2

125. a. 5.11 kg HNO_3 **b.** 154 g NO

126. a. 169 g Al **b.** 7.11 mL Fe(*l*)

127. a. 45.2 g HCl, 9.92 g O_2

b. 19.2 L O_2

128. a. 1.46 g HF, 4.99 g $CaSO_4$

b. 1.95 kg CaF_2

129. a. $2N_2O_5 \rightarrow O_2 + 4NO_2$

b. 0.593 g O_2, 3.41 g NO_2

130. a. 2.38×10^3 g Cl_2 **b.** 201 dL Cl_2

131. a. $2C_2H_4O + O_2 \rightarrow 2C_2H_4O_2$

b. 197 g O_2

Chapter 12 (continued)

123. Balance the equation for the formation of aluminum hydroxide, a common ingredient in some antacid tablets.

$$Al_2(SO_4)_3(aq) + NaOH(aq) \longrightarrow Al(OH)_3(s) + Na_2SO_4(aq)$$

a. How many grams of sodium hydroxide are required to react completely with 6.22 g of aluminum sulfate?

b. When 32.0 grams of sodium hydroxide reacts with an excess of aluminum sulfate, how many grams of aluminum hydroxide are formed?

124. One source of elemental oxygen in the laboratory is the decomposition of hydrogen peroxide.

$$2H_2O_2(l) \longrightarrow 2H_2O(l) + O_2(g)$$

a. How many grams of hydrogen peroxide are needed to produce 5.00 g of oxygen?

b. When 16.8 g of hydrogen peroxide are decomposed, how many liters (at STP) of oxygen are produced?

125. One source of acid rain is the production of nitric acid from nitrogen dioxide and water in the atmosphere.

$$3NO_2(g) + H_2O(l) \longrightarrow NO(g) + 2HNO_3(aq)$$

a. How many kilograms of nitric acid are produced when 5.60 kg of nitrogen dioxide reacts with an excess of water?

b. Calculate the mass in grams of nitrogen monoxide produced when 0.648 kg of nitric acid is formed by this reaction.

126. Steel rails for trains are welded together with the liquid (molten) iron formed by the immense heat generated by this reaction.

$$2Al(s) + Fe_2O_3(s) \longrightarrow Al_2O_3(s) + 2Fe(l)$$

a. How many grams of aluminum are needed to react completely with 0.500 kg of iron(III) oxide?

b. How many milliliters of molten iron are produced when 80.0 g of iron(III) oxide are reacted with an excess of aluminum? The density of iron is 7.87 g/cm^3. Assume the densities of molten iron and solid iron are the same.

127. Chlorine gas is made by reacting oxygen with hydrochloric acid.

$$4HCl(aq) + O_2(g) \longrightarrow 2Cl_2(g) + 2H_2O(l)$$

a. How many grams of each of the reactants are required to produce 44.0 g of chlorine?

b. At STP, how many liters of oxygen are needed to react completely with 125 g of hydrochloric acid?

128. Hydrogen fluoride is made by reacting sulfuric acid with calcium fluoride.

$$H_2SO_4(l) + CaF_2(s) \longrightarrow 2HF(g) + CaSO_4(s)$$

a. How many grams of hydrogen fluoride and calcium sulfate are produced when 2.86 g of calcium fluoride reacts with an excess of sulfuric acid?

b. Calculate the number of kilograms of calcium fluoride that must react with an excess of sulfuric acid to produce 1.00 kg of hydrogen fluoride.

129. When solid dinitrogen pentoxide is heated, it produces oxygen and nitrogen dioxide.

a. Write the balanced equation for this reaction.

b. How many grams of each product are formed when 4.00 g of dinitrogen pentoxide is completely decomposed?

130. Laundry bleach (NaClO) is made by reacting chlorine with sodium hydroxide.

$$Cl_2(g) + 2NaOH(aq) \longrightarrow NaClO(aq) + NaCl(aq) + H_2O(l)$$

a. How many grams of chlorine must react with an excess of sodium hydroxide to produce 2.50 kg of sodium hypochlorite?

b. At room temperature, chlorine gas has a density of 2.95 g/L. How many dL of chlorine gas are needed to react completely with 66.8 g of sodium hydroxide?

131. Bubbling oxygen gas through liquid acetaldehyde (C_2H_4O) forms a single product, acetic acid.

a. Write a balanced equation for this reaction.

b. How many grams of oxygen are needed to react completely with 542 g of acetaldehyde?

132. Water is decomposed into its elements by an electric current.

a. Write a balanced equation for the reaction.

b. What is the total volume (in liters at STP) of gases produced when 222 g of water are decomposed?

133. Oxygen is generated in a rebreathing gas mask by a reaction of water vapor with potassium superoxide, KO_2.

$$4KO_2(s) + 2H_2O(l) \longrightarrow 3O_2(g) + 4KOH(s)$$

a. How many liters of oxygen gas at STP are produced when 56.0 g of potassium superoxide react completely with water vapor?

b. How many grams of potassium hydroxide are produced when the 56.0 g of KO_2 react with an excess of water?

134. Find the limiting reagent for each set of reactants. Then calculate the number of moles of each reactant remaining and the amount of each product formed after the reaction.

$$4NH_3(g) + 3O_2(g) \longrightarrow 2N_2(g) + 6H_2O(l)$$

a. 4.00 mol NH_3 + 4.00 mol O_2

b. 2.00 mol NH_3 + 1.00 mol O_2

c. 7.00 mol NH_3 + 5.00 mol O_2

d. 3.25 mol NH_3 + 2.75 mol O_2

135. Diboron trioxide is formed by reacting 14.0 g of diboron hexahydride with 68.0 g of oxygen.

$$B_2H_6(g) + 3O_2(g) \longrightarrow 3H_2O(l) + B_2O_3(s)$$

a. Identify the limiting reagent.

b. Calculate the mass of diboron trioxide produced.

136. When hydrochloric acid is added to calcium carbonate, bubbles of carbon dioxide gas are produced.

$$CaCO_3(s) + 2HCl(aq) \longrightarrow CaCl_2(aq) + H_2O(l) + CO_2(g)$$

a. What is the limiting reagent when 1.68 g of HCl is added to 4.82 g $CaCO_3$?

b. In the reaction, how many milliliters of water are produced? (density = 1.00 g/cm^3)

c. What is the volume, in liters, of carbon dioxide produced? Assume STP.

137. The elements phosphorus and chlorine react to form phosphorus trichloride.

$$P_4(s) + 6Cl_2(g) \longrightarrow 4PCl_3(l)$$

a. What is the limiting reagent when 100.0 g of phosphorus reacts with 200.0 g of chlorine?

b. How many grams of phosphorus trichloride are formed?

138. Hydrogen gas is one of the products of the reaction of aluminum with hydrochloric acid.

$$2Al(s) + 6HCl(aq) \longrightarrow AlCl_3(aq) + 3H_2(g)$$

How many grams of H_2 are produced when 20.0 g of Al reacts with 60.0 g of HCl?

139. When copper(I) oxide, Cu_2O, is heated in oxygen, copper(II) oxide is formed.

$$2Cu_2O(s) + O_2(g) \longrightarrow 4CuO(s)$$

When 4.00 mol of copper(I) oxide reacts with 2.00 mol of oxygen, 7.44 mol of CuO is obtained. What is the percent yield of this reaction?

140. When 7.00 mol C reacts with 5.00 mol SO_2, 1.80 mol CS_2 is formed.

$$3C(s) + 2SO_2(g) \longrightarrow CS_2(l) + 2CO_2(g)$$

What is the percent yield of this reaction?

141. An excess of water is reacted with 25.0 g of calcium carbide. A mass of 7.20 g of C_2H_2 is obtained.

$$CaC_2(s) + 2H_2O(l) \longrightarrow C_2H_2(g) + Ca(OH)_2(aq)$$

What is the percent yield of C_2H_2?

142. An excess of sulfur dioxide was reacted with 0.150 g of oxygen gas. A mass of 0.725 g of sulfur trioxide was recovered.

$$2SO_2(g) + O_2(g) \longrightarrow 2SO_3(g)$$

What is the percent yield of sulfur trioxide?

143. When 30.0 g CH_4 reacts with 90.0 g O_2 and 30.0 g NH_3, 94.4 g H_2O is formed.

$$2CH_4(g) + 3O_2(g) + 2NH_3(g) \longrightarrow 2HCN(g) + 6H_2O(l)$$

What is the percent yield of this reaction?

132. **a.** $2H_2O \rightarrow 2H_2 + O_2$

b. 829 L

133. **a.** 13.2 L **b.** 44.2 g KOH

134. **a.** limiting reagent is NH_3; after reaction: 0.0 mol NH_3, 1.00 mol O_2, 2.00 mol N_2, and 6 mol H_2O

b. limiting reagent is O_2; after reaction: 0.67 mol NH_3, 0.0 mol O_2, 0.67 mol N_2, 2.00 mol H_2O

c. limiting reagent is O_2; after reaction: 0.33 mol NH_3, 0.0 mol O_2, 3.33 mol N_2, 10.00 mol H_2O

d. limiting reagent is NH_3; after reaction: 0.0 mol NH_3, 0.31 mol O_2, 1.63 mol N_2, and 4.88 mol H_2O

135. **a.** B_2H_6 is limiting **b.** 35.3 g B_2O_3

136. **a.** HCl is limiting **b.** 0.414 mL H_2O **c.** 0.516 L CO_2

137. **a.** chlorine is limiting **b.** 258 g PCl_3

138. 1.64 g H_2

139. 93.0%

140. 77.3%

141. 71.3%

142. 96.5%

143. 99.1%

Chapter 13

144. **a.** 3.59 atm **b.** 109 kPa
c. 198 mm Hg **d.** 2.05 atm
e. 644 mm Hg **f.** 44.6 kPa

145. The intermolecular forces are greater in water.

146. The water will evaporate faster in the pie pan because of its greater surface area.

147. The relative amount of liquid and solid would remain unchanged.

Chapter 14

148. 295 k pa

149. 521 L

150. 3.03 mL

151. 427 mL

152. 398°C

153. 922 kPa

154. 36.8 kPa

155. 7.4 kL

156. 1.13 mol N_2

157. **a.** 44.6 L Ne **b.** no

158. 116 kPa

159. 24.6 L F_2

160. 24.1 kPa

161. P_{Ne} = 101 kPa; P_{Ar} = 505 kPa

162. 3.29 L

163. **a.** 743 kPa

b. The pressure would not change.

c. The pressure would double to 1.49×10^3 kPa

Chapter 13

144. Make the following pressure conversions:

a. 364 kPa to atm

b. 815 mm Hg to kPa

c. 0.260 atm to mm Hg

d. 1555 mm Hg to atm

e. 85.8 kPa to mm Hg

f. 0.440 atm to kPa

145. Water evaporates much more slowly at room temperature than acetone. How does the relative strength of intermolecular forces compare in these two compounds?

146. In the same location, equal quantities of water are poured into a drinking glass and a glass pie pan. In which container will the water evaporate first? Explain your choice.

147. Equal masses of liquid and solid wax are placed in an oven maintained at a temperature exactly at the melting point of the wax. How would the relative amounts of liquid and solid wax change over time?

Chapter 14

148. A sample of gas at a pressure of 124 kPa has a volume of 3.00 L. If the gas is compressed to a volume of 1.26 L, what is its new pressure? (Assume constant temperature.)

149. A scuba tank has a volume of 11.0 L. What volume of gas in liters at 0.950 atm is required to completely fill the tank to a pressure of 45.0 atm, assuming no change in the temperature of the gas?

150. A syringe contains 2.60 mL of gas at 20.0°C. What is the volume of gas after the temperature is increased to 68.0°C?

151. A contained gas has a volume of 120.0 mL at −183°C. What volume does this gas occupy at 47.0°C?

152. To what temperature must a contained gas at a pressure of 464 mm Hg and a temperature of 40.0°C be raised to increase the pressure to 994 mm Hg?

153. The pressure of a gas in a cylinder at 27.0°C is 846 kPa. What is the pressure in the cylinder when the temperature is increased to 54.0°C?

154. Calculate the final pressure of a gas initially at 122 kPa pressure that is expanded from 4.50 L at 56°C to 18.0 L at 124°C.

155. A weather balloon has a volume of 3.5 kL at 1.01 atm and 18°C. What is the balloon's volume at a pressure of 0.420 atm and −18°C?

156. A cylinder contains 4.50 L of nitrogen at 35°C and a pressure of 644 kPa. How many moles of N_2 are in the cylinder?

157. A balloon containing 1.46 mol of neon gas has a volume of 36.2 L.

a. Under the same conditions, what is the volume of the balloon if an additional 0.34 mol of Ne is added to the balloon?

b. Would the answer change if 0.34 mol of He were added instead of neon?

158. What is the pressure (in kPa) in a 5.00-L tank containing 0.240 mol of oxygen gas at a temperature of 17°C?

159. Calculate the volume of 0.880 mol of fluorine gas at 26°C and 88.8 kPa.

160. A metal cylinder contains 0.440 mol of nitrogen gas at a pressure of 34.0 kPa. What is the pressure in the container after 0.128 mol of nitrogen are removed?

161. All the neon gas from a 10.0-L container at a pressure of 202 kPa is added to a 20.0-L container of argon at a pressure of 505 kPa. After the transfer, what are the partial pressures of neon and argon?

162. A child buys a balloon filled with 3.50 L of helium on a very hot day when it's 39.0°C outside. Assuming a constant pressure, what is the volume of the balloon when the child brings the balloon home to an air-conditioned house at 20.0°C?

163. Suppose you have a 0.500-L cylinder that contains 0.150 mol of oxygen gas, O_2, at 25°C.

a. What is the pressure inside the cylinder?

b. How would the pressure inside the cylinder change if you substituted 0.150 mol of sulfur dioxide gas, SO_2, for the 0.150 mol of oxygen gas?

c. How would the pressure inside the cylinder change if you added 0.150 mol of sulfur dioxide gas, SO_2, to the oxygen already in the cylinder?

164. In a typical automobile engine, the gas mixture in a cylinder is compressed and the pressure increases from 1.00 atm to 9.50 atm. If the uncompressed volume of the cylinder is 755 mL, what is the volume when fully compressed? (Assume constant temperature.)

165. What is the new pressure when an aerosol can with an initial pressure of 4.50 atm at 25°C is heated in a fire to 650°C?

166. How many moles of air are in the lungs of an average person with a total lung capacity of 3.8 L? Assume that the person is at sea level (1.00 atm) and has a normal body temperature of 37°C.

167. Two containers of equal size are filled with 4.0 g of He and 32.0 g of O_2, respectively. Assuming a constant temperature, would you expect the pressures of these two gases to be identical? Explain your answer.

168. Lithium nitride is formed from its elements.

$$6Li(s) + N_2(g) \longrightarrow 2Li_3N(s)$$

How many milliliters of nitrogen gas at STP are needed to react with 0.246 g of lithium?

169. Nitrogen and hydrogen react to form ammonia.

$$3H_2(g) + N_2(g) \longrightarrow 2NH_3(g)$$

How many liters of hydrogen gas measured at 86.4 kPa pressure and 245°C are needed to react completely with 6.44 g N_2?

170. Auto air bags are inflated by nitrogen gas formed through this decomposition reaction:

$$2NaN_3(s) \longrightarrow 2Na(s) + 3N_2(g)$$

How many grams of NaN_3 are needed to inflate an air bag to a volume of 10.6 L, assuming STP?

Chapter 15

171. Which of these molecules can form hydrogen bonds with water?

a. H_2 **c.** HCl
b. CH_3OH **d.** C_2H_6

172. Classify each substance as an electrolyte or a nonelectrolyte.

a. NH_4NO_3 **c.** $NaBr_2$
b. C_2H_6O **d.** Cl_2

173. Calculate the percent by mass of water in lithium perchlorate trihydrate.

174. An experiment requires making a solution that contains 34.6 g of $CaCl_2$. Your only source is the hydrate, $CaCl_2 \cdot 2H_2O$. How many grams of the hydrate do you need to use to obtain the required mass of $CaCl_2$?

175. A 19.97-g sample of a hydrate contains 5.08 g Cu, 2.57 g S, 5.12 g O, and 7.20 g H_2O. What is the empirical formula of this hydrate?

Chapter 16

176. The solubility of carbon dioxide gas at 50°C and 1.00 atm pressure is 7.6×10^{-2} g/100 g H_2O. Assuming constant temperature, calculate the solubility of CO_2 when the pressure is increased to 2.50 atm.

177. Calculate the molarity of each of these solutions.

a. 4.24 mol NaCl in 2.00 L of solution
b. 0.164 mol of $C_5H_{10}O_5$ in 125 mL of solution
c. 0.0056 mol CsBr in 50.0 mL of solution
d. 2.84 mol C_2H_6O in 0.650 L of solution

178. What is the molarity of each of these solutions?

a. 3.34 g $CuNO_2$ in 0.150 L of solution
b. 0.0688 g CoF_2 in 20.0 mL of solution
c. 88.8 g KOH in 0.755 L of solution
d. 1.66 g $LiNO_3$ in 455 mL of solution

179. Find the moles of solute in the following solutions:

a. 650 mL of 0.28*M* $NaNO_3$
b. 1.4 L of 0.35*M* KI
c. 0.340 L of 2.22*M* $CaCl_2$
d. 148 mL of 0.0068*M* LiF

180. Calculate the mass of solute in each of these solutions.

a. 2.00 L of 0.440*M* MgF_2
b. 6.80 dL of 1.88*M* CH_4O
c. 65.0 mL of 0.0360*M* $NaNO_3$
d. 5.00 mL of 1.48*M* HCl

164. 79.5 mL

165. 13.9 atm

166. 0.15 mol

167. Yes, because the masses are 1.00 mol of each gas, and equal moles of gases at the same temperature have the same volume.

168. 133 mL N_2

169. 34.4 L H_2

170. 20.5 g NaN_3

Chapter 15

171. **a.** cannot **b.** can
c. can **d.** cannot

172. **a.** electrolyte **b.** nonelectrolyte
c. electrolyte **d.** nonelectrolyte

173. 33.7%

174. 45.8 g $CaCl_2 \cdot 2H_2O$

175. $CuSO_4 \cdot 5H_2O$

Chapter 16

176. 0.19 g/100 g H_2O

177. **a.** 2.12*M* **b.** 1.31*M**
c. 0.11*M* **d.** 4.37*M*

178. **a.** 0.203*M* **b.** $3.55 \times 10^{-2}M$
c. 2.10*M* **d.** $5.29 \times 10^{-2}M$

179. **a.** 0.18 mol $NaNO_3$ **b.** 0.49 mol KI
c. 0.755 mol $Ca(OH)_2$ **d.** 1.01×10^{-3} mol LiF

180. **a.** 54.8 g MgF_2 **b.** 40.9 g CH_3OH
c. 0.199 g $NaNO_3$ **d.** 0.270 g HCl

181. **a.** 20.0 mL **b.** 160 mL
c. 75 mL **d.** 38.0 mL

182. 63 mL of alcohol

183. **a.** 2.39% CsI **b.** 17.6% NaOH
c. 4.75% K_2CO_3 **d.** 37.5% $NaNO_3$

184. **a.** 0.309 CH_4O and 0.691 C_2H_6O
b. 0.342 H_2O and 0.658 HCl
c. 0.484 C_2H_6O and 0.516 H_2O
d. 0.120 C_2H_6O and 0.880 CH_4O

185. **a.** true **b.** false
c. false

186. **a.** 0.148*m* KCl **b.** 0.137*m* $LiNO_3$
c. 5.34×10^{-2}*m* CsI **d.** 2.66*m* $MgBr_2$

187. **a.** f.p. = –8.70°C; b.p. = 102.40°C
b. f.p. = –6.53°C; b.p. = 101.80°C
c. f.p. = –5.36°C; b.p. = 101.47°C
d. f.p. = –2.19°C; b.p. = 100.60°C

188. **a.** 76.2 mL of 0.366*M* $Ni(NO_3)_2$
b. 3.31 g $NiCO_3$

189. **a.** 38.2 mL $Al_2(SO_4)_3(aq)$
b. 0.811 g $Al(OH)_3$

190. **a.** KCl and NaOH, because they both dissociate to give two particles/formula unit in solution.
b. Since $AlCl_3$ dissociates to give 4 particles/formula unit and KCl dissociates to give 2 particles/formula unit, the conductivity of the aluminum chloride solution should be about twice that of the potassium chloride solution.

181. How many milliliters of a stock solution of 2.50*M* $SrCl_2$ solution are required to make each diluted solution?
a. 50.0 mL of 1.00*M* $SrCl_2$
b. 1.0 L of 0.40*M* $SrCl_2$
c. 750 mL of 0.25*M* $SrCl_2$
d. 65.0 dL of 0.146*M* $SrCl_2$

182. An aqueous solution is 65% (v/v) rubbing alcohol. How many milliliters of alcohol are in a 97-mL sample of this solution?

183. Calculate the percent by mass of each of these solutions.
a. 6.50 g CsI in 266 g H_2O
b. 246 g NaOH in 1.40 kg H_2O
c. 0.428 g K_2CO_3 in 8.58 g H_2O
d. 1.20 kg $NaNO_3$ in 2.00 kg H_2O

184. Calculate the mole fraction of each component of the following solutions:
a. 2.40 mol CH_4O and 5.36 mol C_2H_6O
b. 1.25 mol H_2O and 87.6 g HCl
c. 24.0 g C_2H_6O and 10.0 g H_2O
d. 0.464 g C_2H_6O and 2.36 g CH_4O

185. Potassium bromide is dissolved in water. Which statements are true when comparing the solution to pure water?
a. The boiling point of the solution is higher.
b. The vapor pressure of the solution is higher.
c. The freezing point of the solution is higher.

186. Calculate the molality of these solutions.
a. 0.246 mol KCl in 1.66 kg solvent
b. 0.116 mol $LiNO_3$ in 844 g solvent
c. 56.6 mmol CsI in 1.06 kg solvent
d. 6.66 mol $MgBr_2$ in 2.50 kg solvent

187. Calculate the freezing and boiling points of each of these aqueous solutions.
a. 2.34*m* NH_4Br
b. 1.17*m* $CaCl_2$
c. 24.4 g LiCl in 0.400 kg H_2O
d. 44.8 g $MgCl_2$ in 1.20 kg H_2O

188. When aqueous solutions of sodium carbonate and nickel(II) nitrate are mixed, nickel(II) carbonate precipitates.

$$Ni(NO_3)_2(aq) + Na_2CO_3(aq) \longrightarrow NiCO_3(s) + 2NaNO_3(aq)$$

a. What volume of 0.366*M* $Ni(NO_3)_2$ is required to completely react with 55.8 mL of 0.500*M* Na_2CO_3?
b. How many grams of nickel(II) carbonate precipitate in this reaction?

189. Aluminum hydroxide precipitates when aqueous solutions of aluminum sulfate and sodium hydroxide are mixed.

$$Al_2(SO_4)_3(aq) + 6NaOH(aq) \longrightarrow 2Al(OH)_3(s) + 3Na_2SO_4(aq)$$

a. What volume of 0.136*M* $Al_2(SO_4)_3$ is needed to completely react with 26.0 mL of 1.20*M* NaOH?
b. What mass of aluminum hydroxide precipitates in this reaction?

190. A conductivity meter quantitatively measures the ability of an aqueous solution to conduct electrical current. The magnitude of the conductivity value is proportional to the number of ions in the solution. Data from an experiment are given in the table.

Solutions (0.2*M*)	Conductivity (μS/cm)
KCl	2050
$AlCl_3$	4500
$CaCl_2$	3540
NaOH	2080
C_2H_6O	0

a. Which two of the solutions have similar conductivities? Why would you expect this?
b. The ratio of the conductivity of the aluminum chloride solution to the conductivity of the potassium chloride solution is approximately two to one. Why would you expect this result?

Chapter 17

191. As the mass of a substance increases,

a. does its heat capacity increase, decrease, or remain constant?

b. does its specific heat increase, decrease, or remain constant?

192. The temperature of a 6.42-gram piece of glass is 15°C. How many calories would it take to increase the temperature of the glass to 96°C? The specific heat of glass is 0.12 cal/(g·°C).

193. Ethanol has a specific heat of 2.43 J/(g·°C). If 468 J of heat is added to 29.0 g of ethanol initially at 25.0°C, what is the final temperature of the liquid?

194. When 1564 J of energy is added to a sample of gold at 25.0°C, the temperature of the gold increases by 424.0°C. What is the mass of the gold? The specific heat of gold is 0.129 J/(g·°C).

195. Identical masses of aluminum and lead at the same temperature absorb identical amounts of heat energy. The specific heat of aluminum is 0.901 J/(g·°C); the specific heat of lead is 0.129 J/(g·°C). Which gets hotter, the aluminum or the lead?

196. Suppose your diet provides 2100 Cal (kcal) in a day, and your body weight is 68 kg. Start with an initial body temperature of a normal 37°C. Calculate the maximum temperature that your body would reach by absorbing all 2100 kcal at once. For purposes of this problem, assume that your body is 100% water. The specific heat of water is 1.00 cal/(g·°C).

197. Nitrogen monoxide is formed from its elements.

$$N_2(g) + O_2(g) \longrightarrow 2NO(g)$$
$$\Delta H = 181 \text{ kJ/mol}$$

a. Is this reaction exothermic or endothermic?

b. How many kilojoules of energy are needed to form 8.70 mol NO?

198. Carbon dioxide and water are produced by the complete combustion of propane, C_3H_8.

$$C_3H_8(g) + 5O_2(g) \longrightarrow 3CO_2(g) + 4H_2O(g) + 526 \text{ kcal}$$

a. Is this reaction exothermic or endothermic?

b. How many kcal of energy are produced when 14.4 g C_3H_8 burns in an excess of oxygen?

199. The following reaction was used to fuel the rockets in the Apollo mission landing module.

$$2N_2H_4(l) + N_2O_4(l) \longrightarrow 3N_2(g) + 4H_2O(g)$$
$$\Delta H = -1049 \text{ kJ}$$

a. Is this reaction endothermic or exothermic?

b. How many grams of N_2H_4 must be reacted with an excess of N_2O_4 to produce 645 kJ of energy?

c. How many kilojoules of energy are produced when 5.40 g N_2O_4 reacts with an excess of N_2H_4?

200. The heat of fusion of mercury is 2.30 kJ/mol. How much heat (in J) is released when 24.0 g Hg changes from the liquid state to the solid state at its freezing point?

201. How much heat energy is required to change 50.0 g of liquid water at 100°C to water vapor at 100°C? The molar heat of fusion is 6.01 kJ/mol, and the molar heat of vaporization is 40.7 kJ/mol.

202. There is a dramatic temperature change when solid ammonium nitrate is dissolved in water.

$$NH_4NO_3(s) \longrightarrow NH_4^+(aq) + NO_3^-(aq)$$
$$\Delta H_{soln} = 25.7 \text{kJ/mol}$$

a. Is there a temperature increase or decrease when ammonium nitrate dissolves in water?

b. Calculate the heat change when 55.0 g $NH_4NO_3(s)$ dissolves in water.

203. Use the data in Table 17.4 and the additional values for $\Delta H°$ given below to calculate the standard heat of reaction ($\Delta H°$) for each of these reactions.

Substance	$\Delta H_f°$ (kJ/mol)
$N_2H_4(l)$	50.63
$HNO_3(aq)$	−207.4

a. $2SO_2(g) + O_2(g) \longrightarrow 2SO_3(g)$

b. $3N_2H_4(l) \longrightarrow 4NH_3(g) + N_2(g)$

c. $3NO_2(g) + H_2O(g) \longrightarrow 2HNO_3(aq) + NO(g)$

d. $2NO(g) + 2CO(g) \longrightarrow 2CO_2(g) + N_2(g)$

PROBLEM BANK

Chapter 17

191. **a.** increase **b.** remain constant

192. 62 cal

193. 31.6°C

194. 28.6 g

195. lead

196. 68°C

197. **a.** endothermic **b.** 787 kJ

198. **a.** exothermic **b.** 172 kcal

199. **a.** exothermic **b.** 39.4 g N_2H_4 **c.** 61.6 kJ

200. 275 J

201. 113 kJ

202. **a.** decrease **b.** 17.7 kJ

203. **a.** −197.8 kJ **b.** −336.7 kJ **c.** −184.2 kJ **d.** −746.7 kJ

204. –44 kJ

205. –188 kJ/mol

206. 82.3 g H_2O

Chapter 18

207. rate = $[NO]^3[H_2]$

208. **a.** reactants **b.** products
c. reactants **d.** products

209. **a.** $K_{eq} = \dfrac{[POCl_3]^2}{[PCl_3]^2 \times [O_2]}$

b. $K_{eq} = \dfrac{[Cl_2O] \times [H_2O]}{[HOCl]_2}$

c. $K_{eq} = \dfrac{[BrF_5]^2}{[Br_2] \times [F_2]^5}$

d. $K_{eq} = \dfrac{[NO_2]^2 \times [H_2O]^8}{[N_2H_4] \times [H_2O_2]}$

210. **a.** $K_{eq} = 2.26$ **b.** $K_{eq} = 659$
c. $K_{eq} = 4.32 \times 10^{-2}$ **d.** $K_{eq} = 3.60 \times 10^{6}$

211. add more CO; add more H_2, remove CH_4O as it forms, cool the reaction.

212. **a.** the color turns more yellowish
b. the color turns more yellowish

213. **a.** the color turns more bluish
b. the color turns more pinkish

214. **a.** yes **b.** yes
c. yes **d.** no

204. Ethanol is manufactured by reacting water with ethane, C_2H_4.

$$C_2H_4(g) + H_2O(l) \longrightarrow C_2H_6O(l)$$

Use the following equations to calculate the $\Delta H°$ for this reaction.

$$C_2H_6O(l) + 3O_2(g) \longrightarrow 2CO_2(g) + 3H_2O(l) \quad \Delta H = -1367 \text{ kJ}$$

$$C_2H_4(g) + 3O_2(g) \longrightarrow 2CO_2(g) + 2H_2O(l) \quad \Delta H = -1411 \text{ kJ}$$

205. Use the following equations to calculate the standard heat of formation, in kJ/mol, of magnesium nitrate:

$$2MgO(s) \longrightarrow 2Mg(s) + O_2(g) \quad \Delta H = 1203 \text{ kJ}$$

$$Mg_3N_2(s) \longrightarrow 3Mg(s) + N_2(g) \quad \Delta H = 463 \text{ kJ}$$

$$Mg(NO_3)_2(s) + 8Mg(s) \longrightarrow 6MgO(s) + Mg_3N_2(s) \quad \Delta H = -3884 \text{ kJ}$$

206. The heat of sublimation of dry ice (solid CO_2) is 25.2 kJ/mol. How many grams of water at 0.0°C would be frozen by the complete sublimation of 48.0 g of dry ice that is dropped into the water? The heat of fusion of water is 6.01 kJ/mol.

Chapter 18

207. Nitric oxide reacts with hydrogen to form nitrogen gas and water.

$$2NO(g) + 2H_2(g) \longrightarrow N_2(g) + 2H_2O(g)$$

In an experiment, doubling the H_2 concentration causes the rate of reaction to double. When the NO concentration is doubled, the rate of the reaction increases by a factor of eight. Write the rate law for the reaction.

208. At equilibrium, are the reactants or the products favored for reactions that have the following equilibrium constants?

a. $K_{eq} = 5.6 \times 10^{-7}$ **c.** $K_{eq} = 5.6 \times 10^{-14}$
b. $K_{eq} = 5.6 \times 10^{21}$ **d.** $K_{eq} = 5.6 \times 10^{5}$

209. Write the expression for the equilibrium constant for each reaction.

a. $2PCl_3(g) + O_2(g) \rightleftharpoons 2POCl_3(g)$

b. $2HOCl(g) \rightleftharpoons Cl_2O(g) + H_2O(g)$

c. $Br_2(g) + 5F_2(g) \rightleftharpoons 2BrF_5(g)$

d. $N_2H_4(g) + 6H_2O_2(g) \rightleftharpoons 2NO_2(g) + 8H_2O(g)$

210. Using the equations in Problem 209, calculate the value of K_{eq} when the following amounts of reactants and products are present in a 1-L container at equilibrium.

a. 1.44 mol PCl_3, 1.44 mol O_2, and 2.60 mol $POCl_3$

b. 0.220 mol HOCl, 4.68 mol Cl_2O, and 6.82 mol H_2O

c. 0.0500 mol Br_2, 1.00 mol F_2, and 0.0465 mol BrF_5

d. 0.400 mol N_2H_4, 0.100 mol H_2O_2, 1.20 mol NO_2, and 1.00 mol H_2O

211. List three ways to cause a shift in this equilibrium to the right, forming more $CH_4O(g)$.

$$CO(g) + 2H_2(g) \rightleftharpoons CH_4O(g) + \text{heat}$$

212. A yellow gas (Y) reacts with a colorless gas (C) to produce a blue gas (B), according to this equation:

$$C(g) + 3Y(g) \rightleftharpoons 2B(g) + \text{heat}$$

The system is initially at equilibrium and has a green color. What happens to the color of the system if the following stresses are placed on the system? Note: Blue and yellow mix to form green.

a. A large amount of colorless C is removed from the reaction container.

b. The reaction container is heated.

213. Assume that the following chemical system is originally at equilibrium and the color of the liquid is purplish (a mixture of the colors pink and blue):

$$\text{heat} + \underset{\text{pink}}{[Co(H_2O)_6]^{2+}(aq)} + 4\ Cl^-(aq) \rightleftharpoons \underset{\text{blue}}{[CoCl_4]^{2-}(aq)} + 6\ H_2O(l)$$

a. How does the color change if chloride ion is added to the system?

b. How does the color change if the reaction mixture is cooled?

214. Use Table 18.1 to predict whether a precipitate will form when the following pairs of substances are mixed.

a. $K_2S(aq) + Cu(NO_3)_2(aq)$

b. $NH_4Cl(aq) + Pb(NO_3)_2(aq)$

c. $Na_2CO_3(aq) + ZnCl_2(aq)$

d. $KNO_3(aq) + BaCl_2(aq)$

215. Find the equilibrium concentrations of zinc and sulfide ions in a saturated solution of zinc sulfide with $K_{sp} = 3.0 \times 10^{-23}$.

216. For each change, does the entropy increase or decrease?

a. A gold nugget melts.

b. Liquid wax solidifies.

c. Liquid water forms from water vapor.

d. Liquid water forms from hydrogen and oxygen gas.

Chapter 19

217. Identify each of the species in each equation as a Brønsted-Lowry acid or a Brønsted-Lowry base.

a. $H_2O(aq) + CN^-(aq) \rightleftharpoons OH\ (aq) + HCN(aq)$

b. $HClO_3(aq) + H_2O(aq) \rightleftharpoons ClO_3^-(aq) + H_3O^+(aq)$

c. $C_5H_5NH^+(aq) + OH^-(aq) \rightleftharpoons C_5H_5N(aq) + H_2O(aq)$

d. $HSO_4^-(aq) + H_3O^+(aq) \rightleftharpoons H_2SO_4(aq) + H_2O(aq)$

218. Which of the following are conjugate acid-base pairs?

a. NH_4^+, NH_3

b. H_3PO_4, $H_2PO_4^-$

c. HSO_4^-, SO_4^{2-}

d. H_3O^+, OH^-

219. Ammonia can act as a Lewis base toward which of these compounds?

a. CH_4

b. BCl_3

c. NF_3

d. OF_2

220. Calculate the pH of each solution and classify it as acidic or basic.

a. $[H^+] = 4.6 \times 10^{-4} M$

b. $[H^+] = 1.2 \times 10^{-8} M$

c. $[OH^-] = 8.3 \times 10^{-4} M$

d. $[OH^-] = 2.8 \times 10^{-11} M$

e. $[H^+] = 3.9 \times 10^{-2} M$

f. $[OH^-] = 1.5 \times 10^{-9} M$

221. Calculate the $[H^+]$ and the $[OH^-]$ from the pH of each solution.

a. pH = 6.03

b. pH = 1.18

c. pH = 12.68

d. pH = 4.33

e. pH = 9.16

f. pH = 3.46

222. Rank these acids from strongest to weakest.

a. HX, $K_a = 1 \times 10^{-4}$

b. HY, $K_a = 1 \times 10^{-11}$

c. HP, $K_a = 1 \times 10^{-2}$

d. HQ, $K_a = 1 \times 10^{-9}$

223. Acetylsalicylic acid (aspirin) has a K_a of 3×10^{-4}. A 0.00056*M* solution of aspirin would be best described by which terms: weak, strong, dilute, concentrated?

224. A 0.10000*M* solution of an unknown acid, HX, has a hydrogen ion concentration of $3.65 \times 10^{-4} M$. Calculate the value of K_a for this acid.

225. Name and write the formula for the salt formed in each of the following acid-base neutralizations.

a. aluminum hydroxide with phosphoric acid

b. oxalic acid with magnesium hydroxide

c. sulfurous acid with lithium hydroxide

d. sodium hydroxide with carbonic acid

226. How many moles of sulfuric acid are required to neutralize 1.40 mol of potassium hydroxide?

$2KOH(aq) + H_2SO_4(aq) \longrightarrow K_2SO_4(aq) + 2H_2O(l)$

227. What is the molarity of a hydrochloric acid solution if 25.0 mL of the solution reacts completely with 1.66 g $NaHCO_3$?

$HCl(aq) + NaHCO_3(s) \longrightarrow NaCl(aq) + H_2O(l) + CO_2(g)$

228. In an acid base titration, how many mL of 0.180*M* HCl are required to neutralize 20.0 mL of 0.220*M* NaOH?

229. How many milliliters of 0.456*M* $Ca(OH)_2$ are needed to neutralize 25.0 mL of 0.300*M* HCl?

215. $[Zn^{2+}] = [S^{2-}] = 5.5 \times 10^{-12}\ M$

216. **a.** increase **b.** decrease
c. decrease **d.** decrease

Chapter 19

217. **a.** $H_2O(aq) + CN^-(aq) \leftrightarrows OH^-(aq) + HCN(aq)$
acid base base acid

b. $HClO_3(aq) + H_2O(aq) \leftrightarrows ClO_3^-(aq) + H_3O^+(aq)$
acid base base acid

c. $C_5H_5NH^+(aq) + OH^-(aq) \leftrightarrows C_5H_5N(aq) + H_2O(aq)$
acid base base acid

d. $HSO_4^-(aq) + H_3O^+(aq) \leftrightarrows H_2SO_4(aq) + H_2O(aq)$
acid base base acid

218. **a.** yes **b.** yes
c. yes **d.** no

219. **a.** no **b.** yes
c. no **d.** no

220. **a.** 3.34, acidic **b.** 7.92, basic
c. 10.92, basic **d.** 3.45, acidic
e. 1.41, acidic **f.** 5.18, acidic

221 **a.** $[H^+] = 9.3 \times 10^{-7} M$, $[OH^-] = 1.1 \times 10^{-8} M$

b. $[H^+] = 6.6 \times 10^{-2} M$, $[OH^-] = 1.5 \times 10^{-13} M$

c. $[H^+] = 2.1 \times 10^{-13} M$, $[OH^-] = 4.8 \times 10^{-2} M$

d. $[H^+] = 4.7 \times 10^{-5} M$, $[OH^-] = 2.1 \times 10^{-10} M$

e. $[H^+] = 6.9 \times 10^{-10} M$, $[OH^-] = 1.4 \times 10^{-5} M$

f. $[H^+] = 3.5 \times 10^{-4} M$, $[OH^-] = 2.9 \times 10^{-11} M$

222. **c.** > **a.** > **d.** > **b.**

223. a dilute solution of a weak acid

224. 1.34×10^{-6}

225. **a.** aluminum phosphate, $AlPO_4$

b. magnesium oxalate, MgC_2O_4

c. lithium sulfite, Li_2SO_3

d. sodium carbonate, Na_2CO_3

226. 0.700 mol H_2SO_4

227. 0.790*M* HCl

228. 24.4 ml HCl

229. 8.22 mL $Ca(OH)_2$

230. a. $BrO^- + H^+ \rightarrow HBrO$

b. $HBrO + OH^- \rightarrow BrO^- + H_2O$

Chapter 20

231. a. +6 **b.** +2
c. +4 **d.** +6
e. 0 **f.** +6

232. a. −1 **b.** +5
c. +3 **d.** 0
e. +1 **f.** +1

233. a. Fe **b.** $CuCl_2$
c. Fe **d.** Fe

234. a. oxidized **b.** oxidized
c. reduced **d.** reduced

235. a. $HgS(s) \rightarrow Hg(l) + S(s)$

b. $2S(s) + 3O_2(g) \rightarrow 2SO_3(g)$

c. $H_2SO_4(aq) + 4Ca(s) + 8H^+(aq) \rightarrow H_2S(g) + 4Ca^{2+}(aq) + 4H_2O(l)$

d. $2Al(s) + 3S(s) \rightarrow Al_2S_3(s)$

236. a. $Mg(s) + 2H_2O(l) \rightarrow Mg(OH)_2 + H_2(g)$
single replacement

b. $PF_3(g) + F_2(g) \rightarrow PF_5(g)$
combination

c. $C_2H_2(g) + 2H_2(g) \rightarrow C_2H_6(g)$
combination

d. $2NaNO_3(s) \rightarrow 2NaNO_2(s) + O_2(g)$
decomposition

237. a. Fe, +2; Mn, +7 **b.** S, +6, O, −2
c. MnO_4^- **d.** Mn ion in MnO_4^-

238. a. $2NO + 2H_2 \rightarrow N_2 + 2H_2O$
nitrogen is reduced, hydrogen is oxidized

b. $2KMnO_4 + 10FeSO_4 + 8H_2SO_4 \rightarrow K_2SO_4 + 2MnSO_4 + 5Fe_2(SO_4)_3 + 8H_2O$
manganese is reduced, iron is oxidized

c. $P_4 + 6NO \rightarrow P_4O_6 + 3N_2$
nitrogen is reduced, phosphorus is oxidized

d. $3SO_2 + 2HNO_3 + 2H_2O \rightarrow 3H_2SO_4 + 2NO$
nitrogen is reduced, sulfur is oxidized

239. a. $2KMnO_4(aq) + 3NaNO_2(aq) + H_2O(l) \rightarrow 2MnO_2(s) + 3NaNO_3(aq) + 2KOH(aq)$
oxidizing agent is $KMnO_4$;
reducing agent is $NaNO_2$

b. $I_2(s) + 2Na_2S_2O_3(aq) \rightarrow Na_2S_4O_6(aq) + 2NaI(aq)$
oxidizing agent is I_2;
reducing agent is $Na_2S_2O_3$

c. $6HCl(aq) + 2NH_4Cl(aq) + K_2Cr_2O_7(aq) \rightarrow 2CrCl_3(aq) + 2KCl(aq) + N_2(g) + 7H_2O(l)$
oxidizing agent is $K_2Cr_2O_7$;
reducing agent is NH_4Cl

230. A buffer ($HBrO/BrO^-$) solution is made by mixing together equal quantities of hypobromous acid (HBrO) and sodium hypobromite (NaBrO).

a. Write an equation for the reaction that occurs when an acid is added to this buffer.

b. Write an equation for the reaction that occurs when a base is added to this buffer.

Chapter 20

231. What is the oxidation number of sulfur in each of these species?

a. SF_6 **d.** SO_3
b. CaS_2O_3 **e.** S
c. K_2SO_3 **f.** H_2SO_4

232. What is the oxidation number of bromine in each of the following?

a. CsBr **d.** Br_2
b. $NaBrO_3$ **e.** BrCl
c. BrO_2^- **f.** NaBrO

233. Consider the following reaction:

$$CuCl_2(aq) + Fe(s) \longrightarrow Cu(s) + FeCl_2(aq)$$

a. Which reactant lost electrons?

b. What is the oxidizing agent?

c. Which reactant was oxidized in this reaction?

d. What is the reducing agent?

234. In each of these reactions, is sulfur oxidized or reduced?

a. $HgS(s) \longrightarrow Hg(l) + S(s)$

b. $S(s) + O_2(g) \longrightarrow SO_3(g)$

c. $H_2SO_4(aq) + Ca(s) \longrightarrow H_2S(g) + Ca^{2+}(aq)$

d. $Al(s) + S(s) \longrightarrow Al_2S_3(s)$

235. Balance each of the equations in Problem 234.

236. Balance each of the following redox reactions and classify each as a combination, decomposition, or single-replacement reaction.

a. $Mg(s) + H_2O(l) \longrightarrow Mg(OH)_2 + H_2(g)$

b. $PF_3(g) + F_2(g) \longrightarrow PF_5(g)$

c. $C_2H_2(g) + H_2(g) \longrightarrow C_2H_6(g)$

d. $NaNO_3(s) \longrightarrow NaNO_2(s) + O_2(g)$

237. Iron(II) sulfite reacts with an acid solution of permanganate ion.

$$5FeSO_3 + 14H^+ + 3MnO_4^- \longrightarrow 3Mn^{2+} + 5Fe^{3+} + 5SO_4^{2-} + 7H_2O$$

a. What is the oxidation number of iron and of manganese in the reactants?

b. What is the oxidation number of sulfur and of oxygen in SO_4^{2-}?

c. Identify the oxidizing agent in this reaction.

d. What is reduced in this reaction?

238. Write a balanced chemical equation for each of these reactions, and identify the element oxidized and the element reduced.

a. Nitrogen monoxide reacts with hydrogen to form nitrogen and water.

b. Potassium permanganate, iron(II) sulfate, and sulfuric acid react, producing manganese(II) sulfate, iron(III) sulfate, potassium sulfate, and water.

c. Elemental phosphorus (P_4) and nitrogen monoxide react to form tetraphosphorus hexoxide and nitrogen.

d. Sulfur dioxide, nitric acid, and water react to produce sulfuric acid and nitrogen monoxide.

239. Balance each redox equation by the oxidation-number-change method. Identify the oxidizing agent and the reducing agent.

a. $KMnO_4(aq) + NaNO_2(aq) + H_2O(l) \longrightarrow MnO_2(s) + NaNO_3(aq) + KOH(aq)$

b. $I_2(s) + Na_2S_2O_3(aq) \longrightarrow Na_2S_4O_6(aq) + NaI(aq)$

c. $HCl(aq) + NH_4Cl(aq) + K_2Cr_2O_7(aq) \longrightarrow CrCl_3(aq) + KCl(aq) + N_2(g) + H_2O(l)$

d. $FeCl_2(aq) + H_2O_2(aq) + HCl(aq) \longrightarrow FeCl_3(aq) + H_2O(l)$

240. Use the half-reaction method to write a balanced ionic equation for each reaction. Identify the species oxidized and the species reduced.

a. $Cr_2O_7^{2-}(aq) + I^-(aq) \longrightarrow Cr^{3+}(aq) + I_2(s)$ (in acidic solution)

b. $MnO_4^-(aq) + SO_3^{2-}(aq) \longrightarrow Mn^{2+}(aq) + SO_4^{2-}(aq)$ (in acidic solution)

c. $C_2O_4^{2-}(aq) + MnO_4^-(aq) \longrightarrow CO_3^{2-}(aq) + MnO_2(s)$ (in basic solution)

d. $CN^-(aq) + 2MnO_4^-(aq) \longrightarrow MnO_2(s) + CNO^-(aq)$ (in basic solution)

d. $2FeCl_2(aq) + H_2O_2(aq) + 2HCl(aq) \rightarrow 2FeCl_3(aq) + 2H_2O(l)$
oxidizing agent is H_2O_2;
reducing agent is $FeCl_2$

240. a. $Cr_2O_7^{2-}(aq) + 6I^-(aq) + 14H^+(aq) \rightarrow 2Cr^{3+}(aq) + 3I_2(s) + 7H_2O(l)$
$Cr_2O_7^{2-}$ is reduced; I^- is oxidized

b. $2MnO_4^-(aq) + 5SO_3^{2-}(aq) + 6H^+ \rightarrow 2Mn^{2+}(aq) + 5SO_4^{2-}(aq) + 3H_2O(l)$
MnO_4^- is reduced; SO_3^{2-} is oxidized

c. $3C_2O_4^{2-}(aq) + 2MnO_4^-(aq) + 4OH^-(aq) \rightarrow 6CO_3^{2-}(aq) + 2MnO_2(s) + 2H_2O(l)$
$C_2O_4^{2-}$ is oxidized; MnO_4^- is reduced

d. $3CN^-(aq) + 2MnO_4^-(aq) + H_2O(l) \rightarrow 2MnO_2(s) + 3CNO^-(aq) + 2OH^-(aq)$
CN^- is oxidized; MnO_4^- is reduced

Chapter 21

241. What happens when a strip of zinc is dipped into a solution of aluminum chloride?

242. A strip of aluminum is dipped into a solution of nickel(II) sulfate. Explain the result.

243. A voltaic cell is constructed using the following half-reactions:

$Ag^+(aq) + e^- \longrightarrow Ag(s)$ $\quad E°_{Ag^+} = +0.80\ V$

$Al^{3+}(aq) + 3e^- \longrightarrow Al(s)$ $\quad E°_{Al^{3+}} = -1.66\ V$

Determine the cell reaction.

244. Calculate the standard cell potential for the voltaic cell described in Problem 243.

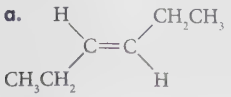
245. What process, reduction or oxidation, always occurs at the anode of an electrolytic cell?

Chapter 22

246. What bonding properties make carbon uniquely suited to make a very large number of organic compounds?

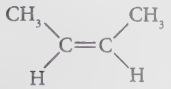
247. Draw structural formulas for these compounds.

a. 3-phenylpentane



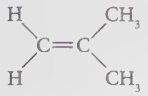
b. 2-phenyl-1-butene

248. Describe the structural features of an alkene molecule that permits the existence of *cis*, *trans* isomers.

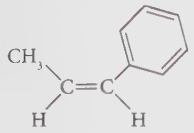


249. How is an asymmetric carbon produced in an organic molecule?

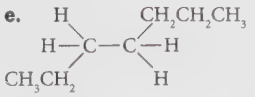
250. Which of these structures are *cis* isomers?



a.

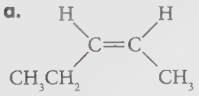


b.

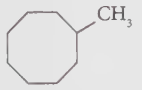


c.

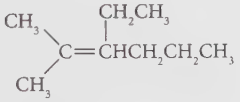
d.



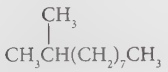
e.



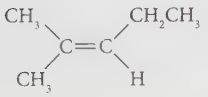
251. Write the IUPAC names for these structures. Use *cis* and *trans* prefixes when appropriate.



a.



b.



c.

d.

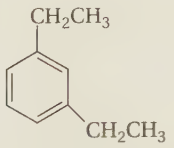
e.

Chapter 21

241. nothing

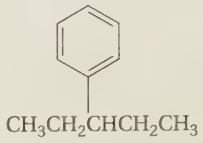
242. The aluminum strip will become nickel plated.

243. $Al(s) + 3Ag^+(aq) \rightarrow Al^{3+}(aq) + 3Ag(s)$



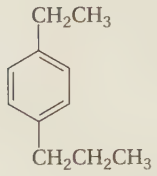
244. Standard cell potential is: +9.66 V

245. oxidation

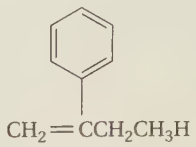


Chapter 22

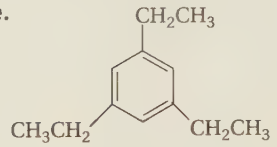
246. the ability of carbon atoms to form four stable covalent bonds with other carbon atoms



247. **a.**



b.



c.

d.

e.

248. carbon–carbon double bond

249. four different groups attached to a carbon atom

250. b., d.

251. **a.** cis-2-pentene **b.** methylcyclooctane
c. 2-methyldecane **d.** 2-methyl-2-pentene
e. 2-methyl-3-ethyl-2-hexene

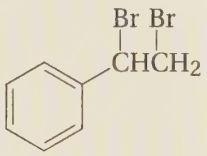
252. phenyl

253. more resistant because the benzene ring is stabilized by resonance

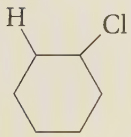
254. a., c., d., e.

256. coal, because it contains aromatic compounds from which benzene can be readily made.

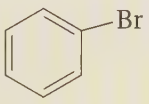
Chapter 23



257. **a.** halogen **b.** carboxyl **c.** amino **d.** carbonyl **e.** ether



258. b., d, e.



259. 84.2 g/mol

260.

a. $CH_2ClCHClCH_2CH_3$

b. 

c. 

d. 

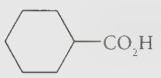
252. What name is given to a benzene ring when it is a substituent in an organic molecule?

253. Are benzene rings more resistant or less resistant to chemical reactions than the carbon-carbon double bond in an alkane? Explain your answer.

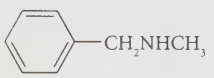
254. Which structural feature(s) characterize alkanes?

- **a.** carbon-hydrogen single bonds
- **b.** carbon-carbon double bonds
- **c.** carbon-carbon single bonds
- **d.** may contain branched chains
- **e.** may contain phenyl substituents

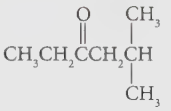
255. Draw structural formulas for these compounds.



- **a.** 1,3-diethylbenzene
- **b.** 1,4-ethylpropylbenzene
- **c.** 1,3,5-triethylbenzene



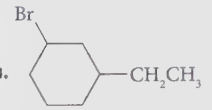
256. If you want to devise an industrial process to prepare methylbenzene, would you prefer petroleum or coal as your starting material? Explain your choice.



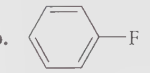
Chapter 23

257. Name the functional group in these molecular structures.

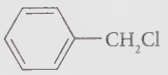
a. CH_3CH_2Br



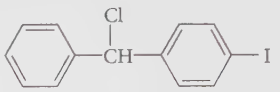
b. 



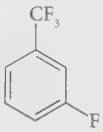
c. 



d. 



e. $CH_3CH_2CH_2OCH_3$

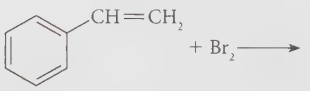


258. Which of these structures represent aryl halides?

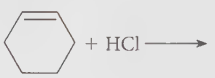
a. 

b. 

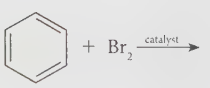
c. 



d. 



e. 

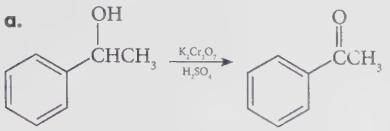


259. If 5.23 g of an alkene is required to completely decolorize 9.92 g of bromine, what is the molar mass of the alkene?

260. Write structural formulas for the organic product of these reactions.

a. $CH_2{=}CHCH_2CH_3 + Cl_2 \longrightarrow$

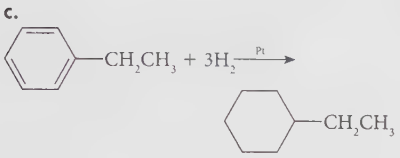
b. 



c. 

d. 

261. Treatment of 7.57 g of pentanoic acid with a large excess of ethanol in the presence of a catalytic amount of hydrochloric acid produced 8.21 g of ethyl pentanoate after purification. Write a balanced equation for the reaction and calculate the percent yield of the ester.



262. Classify these reactions as oxidation or reduction.

a.

b. $CH_3CH_2CH_2CH_2CHO \xrightarrow{CuSO_4} CH_3CH_2CH_2CH_2CO_2H$

c.

d. $CH_4 + 2O_2 \longrightarrow CO_2 + 2H_2O$

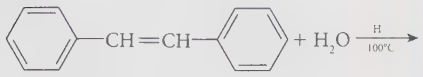
263. How many liters of hydrogen gas at STP are required to saturate 0.150 mole of benzene?

264. Write complete equations for the following organic reactions. Be sure to include all reactants and catalysts required for the transformations.

a. 1-pentene to pentane

b. 2,3-dimethyl-2-butene to 2-chloro-2,3-dimethylbutane

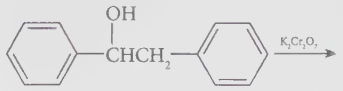
c. ethane to chloroethane



d. cyclohexene to 1,2-dibromocyclohexane

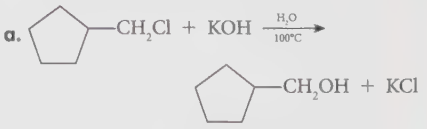
265. A sample of benzaldehyde is oxidized to produce the crystalline white solid, benzoic acid. Write the structural formula of benzoic acid.

266. Complete these reactions.



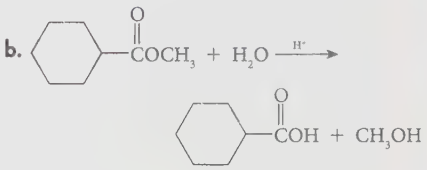
a. $CH_3CH_2CH_2I + KOH \xrightarrow[100°C]{H_2O}$

b.

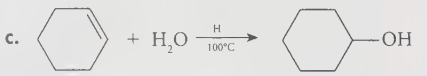


c. $CH_3CH_2CHO \xrightarrow{K_2Cr_2O_7}$

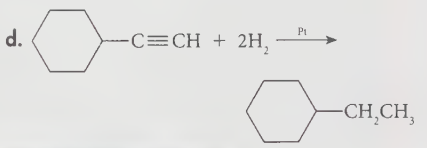
d.



267. Classify each of these reactions as a hydration, hydrogenation, hydrolysis, or substitution.



a.



b.

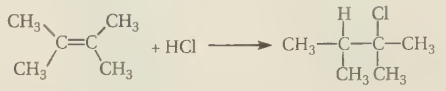
c.

d.

Chapter 24

268. Saliva contains an enzyme called amylase, which catalyzes the breakdown of starch to its monomers. Suggest a reason why a piece of bread begins to taste sweet when it has been chewed for a short time.

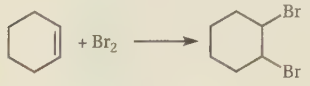
261. $CH_3CH_2CH_2CH_2COOH + CH_3CH_2OH \xrightarrow{HCl} CH_3CH_2CH_2CH_2COOCH_2CH_3$



85.1% yield of ethyl pentanoate

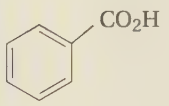
262. **a.** oxidation **b.** oxidation **c.** reduction **d.** oxidation

263. 10.1 L



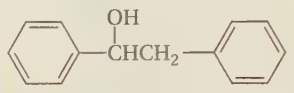
264. **a.** $CH_2{=}CHCH_2CH_2CH_3 + H_2 \xrightarrow{Pt} CH_3CH_2CH_2CH_2CH_3$

b.

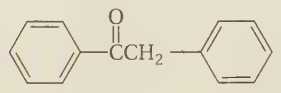


c. $CH_3CH_3 + Cl_2 \xrightarrow{UV\ light} CH_3CH_2Cl + HCl$

d.



265.



266. **a.** $CH_3CH_2CH_2OH + KI$

b.

c. CH_3CH_2COOH

d.

267. **a.** substitution **b.** hydrolysis **c.** hydration **d.** hydrogenation

Chapter 24

268. Action of amylase breaks down starch to its glucose monomers; glucose tastes sweet.

269. a., b., c.

270. 1.67×10^{17} minutes; 2.78×10^{15} hours

271. 4.1 g

272. **a.** 342.0 g/mol **b.** $2.08 \times 10^{-2} M$
c. $C_{12}H_{22}O_{11} + 12O_2 \rightarrow 12CO_2 + 11H_2O$

273. **a.** 23.0 g **b.** 8.67×10^2 kJ
c. 2.07×10^2 Cal **d.** 10.4%

274. 1.87 km

275. 1.5×10^8 turns

276. Add the equations and the free energies to obtain

phosphoenolpyruvic acid + ADP ⟶ ATP + pyruvic acid

$\Delta G = -30.9$ kJ/mol

Transfer of a phosphoryl group from phosphoenolpyruvate to ADP to form ATP is spontaneous.

277. 2.33 mol ATP

Chapter 25

278. The mass number of atom C is 4 less than that of atom A; the atomic number of C is 1 less than that of atom A.

279. $^{133}_{54}\text{Xe} \rightarrow {}^{133}_{55}\text{Cs} + {}^{0}_{-1}\beta$

280. **b.** and **d.** stable; neutron-to-proton ratio in Band of Stability.

281. **a.** $^{26}_{11}\text{Na} \rightarrow {}^{0}_{-1}\beta + {}^{26}_{12}\text{Mg}$

b. $^{234}_{92}\text{U} \rightarrow {}^{4}_{2}\text{He} + {}^{230}_{90}\text{Th}$

282. 1.69×10^5 years

269. Which of these statements apply to enzymes?

a. do not change position of equilibrium

b. catalyze biological reactions

c. bind substrates and sometimes cofactors at active sites

d. change position of equilibrium to favor products

e. are almost always nucleic acids

270. If one molecule of the enzyme catalase can break down 3.60×10^6 peroxide molecules in one minute, how many minutes would it take this enzyme molecule to break down 1 mole of peroxide? How many hours?

271. The level of glucose in the blood is normally 70–120 mg/dL. If a student's volume of blood is 4.5 L and her blood glucose level is 90 mg/dL, what is the total number of grams of glucose in her blood?

272. Sucrose, ordinary table sugar, has the molecular formula $C_{12}H_{22}O_{11}$.

a. What is the molar mass of sucrose?

b. What is the molarity of an aqueous solution containing 7.12 g/L of sucrose?

c. Write a balanced equation for the complete combustion of sucrose in air.

273. A student eats a 115-g hamburger that contains 20.0% by mass of fat. The chemical potential energy of fat is 37.7 kJ/gram.

a. How many grams of fat does the hamburger contain?

b. How many kilojoules of energy are stored in the fat?

c. What is this amount of energy in dietary Calories?

d. What percentage of total Calories does this amount of energy represent in a 2.00×10^3 Calorie/day diet?

274. Walnuts, rich in fats and oils and with a chemical potential energy of 25.8 kJ/g, are a nutritious treat for many people. Suppose you eat 27.3 g of walnuts and then take a brisk walk. If you burn 3.76×10^2 kJ of kinetic energy for each kilometer you walk, how far will you need to walk to use up the energy provided by the walnuts?

275. There are 3.4 base pairs in every complete turn of the double helix in a DNA molecule. How many turns are in a DNA molecule that contains 5.0×10^8 base pairs?

276. ATP is not the only biological molecule capable of transmitting energy. For example, hydrolysis of the molecule phosphoenolpyruvic acid releases even more free energy than the hydrolysis of ATP. Use the equations below to write a net equation showing that the energy released by the hydrolysis of phosphoenolpyruvic acid can be coupled to the phosphorylation of ADP to form ATP in a spontaneous reaction.

Phosphoenolpyruvic acid + H_2O ⟶ pyruvic acid + P_i

$\Delta G = -61.4$ kJ/mol

ADP + P_i + ⟶ ATP + H_2O

$\Delta G = 30.5$ kJ/mol

277. The hydrolysis of ATP to ADP and inorganic phosphate releases 30.5 kJ/mol of free energy. If all of this energy is wasted as heat, how many moles of ATP must be hydrolyzed to raise the temperature of 1 L of water at 20°C to 37°C?

Chapter 25

278. How do the mass number and the atomic number of radioactive atom A change if it first emits an alpha particle and the resulting atom then emits a beta particle to finally give atom C?

279. A radioactive active atom undergoes beta decay to yield cesium-133. Write a balanced equation for this nuclear reaction.

280. Which nuclei would you predict to be stable? Explain your answer.

a. $^{9}_{3}\text{Li}$ **c.** $^{20}_{8}\text{O}$

b. $^{59}_{27}\text{Co}$ **d.** $^{146}_{60}\text{Nd}$

281. Write a balanced nuclear equation for the following:

a. beta decay of sodium-26

b. alpha decay of $^{234}_{92}\text{U}$

282. Plutonium-239 presents a serious nuclear waste disposal problem. If seven half-lives are required for the radioactivity from the waste to reach a tolerable level and if Pu-239 has a $t_{1/2} = 2.41 \times 10^4$ years, how long must the Pu-239 be stored?

Appendix E Selected Solutions

Chapter 1

25. $12 \text{ blocks} \times \frac{1 \text{ m}}{10 \text{ blocks}} \times \frac{20 \text{ min}}{1 \text{ m}} = 24 \text{ min}$

26. $48 \text{ min} \times \frac{1 \text{ m}}{20 \text{ min}} \times \frac{10 \text{ blocks}}{1 \text{ m}} = 20 \text{ blocks}$

27. Algebra II would be scheduled during the 2nd period instead of 1st period.

28. No, Manny's schedule would not change. Algebra II would not be scheduled during 2nd period because Art must be scheduled during this time. Algebra II would not be scheduled during 3rd period because Chemistry must be scheduled during this time. Therefore, Algebra II would still be scheduled during 1st period.

35. Chemistry is concerned with the changes that matter undergoes.

37. A scientist who is studying cancer with the goal of finding an effective treatment is doing applied research because the research is directed toward a practical goal or application.

38. A firefighter needs to know which chemicals to use to fight different types of fires; a knowledge of chemistry will help a reporter gather information during an interview with a chemist.

42. Scientists can study the composition of distant stars by analyzing the light they transmit to Earth.

44. The most powerful tool that any scientist can have is the scientific method.

46. c

48. Repeat the experiment. If you get the same result, you must propose a new hypothesis.

49. A scientific law summarizes the results of many experiments; a theory explains the results of the experiments.

51. Good problem solvers do b, c, and d.

54. Two games won out of three games played means that one game is lost out of three games played:

$162 \text{ games played} \times \frac{1 \text{ loss}}{3 \text{ games played}} = 54 \text{ losses}$

56. $1{,}000{,}000 \text{ pennies} \times \frac{1 \text{ sec}}{1 \text{ penny}} \times \frac{1 \text{ min}}{60 \text{ sec}} \times \frac{1 \text{ h}}{60 \text{ min}} \times \frac{1 \text{ day}}{24 \text{ h}} = 11.6 \text{ days (about 12 days)}$

57. Answers vary; possible answers: 1c, 2d, 3e, 4b, 5a

58. One possible answer is the development of materials to produce artificial limbs.

61. The doctor's hypothesis is that the sore throat is the result of bacteria that cause strep throat. The experiment she performs to test the hypothesis is to test the sample for the presence of the bacteria that causes strep.

62. Your experiment may be correct, but your hypothesis may be wrong. You should reexamine your hypothesis and repeat the experiment.

65. **a.** Independent variable: amount of salt added

b. Dependent variable: freezing point of the salt water

c. Changing the volume of the water would also change the relative amount of salt per volume of water and would affect the results.

d. Yes, to a point. The freezing point appears to be leveling off at about 15°C.

66. $40 \text{ mi by bicycle} \times \frac{30 \text{ mi by car}}{4 \text{ mi by bicycle}} = 300 \text{ mi by car}$

70. A person who is educated in the theories and practice of chemistry is more likely to recognize the significance of an accidental discovery and have the means and motivation to develop that accidental discovery into an important scientific contribution.

71. Method 1: Divide the weight of four beakers by 2; 2.0 lb/2 = 1.0 lb. Method 2: Multiply the weight of one beaker by 2; 0.5 lb × 2 = 1.0 lb. The answers are the same.

72. A theory can never be proven. It is a well-tested explanation of a broad set of observations. A theory may need to be changed in the future to explain new observations.

73. c

75. Number of crates = 5 × 6 × 5 = 150 crates

$$150 \text{ crates} \times \frac{4 \text{ boxes}}{1 \text{ crate}} \times \frac{20 \text{ cartons}}{1 \text{ box}} \times \frac{12 \text{ eggs}}{1 \text{ carton}} = 144{,}000 \text{ eggs}$$

77. **a.** $1 \text{ package} \times \frac{1 \text{ carton}}{6 \text{ packages}} \times \frac{1 \text{ box}}{12 \text{ cartons}} \times \frac{1 \text{ crate}}{8 \text{ boxes}} \times \frac{\$576.00}{1 \text{ crate}} = \$1.00$

b. number of envelopes in a package

Selected Solutions R73

80. Answers will vary, but possible answers are as follows: Factors: (1) PLA is made from natural resources; (2) producing PLA requires less energy than producing petroleum-based plastics; (3) compost facility availability. Factors (1) and (2) make PLA products a good choice, but factor (3) may make it difficult to choose PLA products.

Chapter 2

10. Iron is magnetic; table salt is not. Table salt will dissolve in water; iron will not.

11. By lowering the temperature to below the boiling point of each gas, you could condense each substance and separate the gases.

20. Liquid A is probably a substance. Liquid B is a mixture because a solid remained after evaporation.

21. The liquid was not an element because a solid was left when the liquid evaporated. A physical process, such as evaporation, cannot be used to break down a compound. Therefore, the liquid was a mixture.

42. State; both are gases.

44. A vapor; the term *vapor* is used to refer to the gaseous state of a substance which normally exists as a liquid or solid at room temperature.

47. Sharpening a pencil is an irreversible change. Making ice cubes is a reversible change.

50. **a.** heterogeneous

b. homogeneous

c. depends on how well the batter is mixed

d. homogeneous

e. heterogeneous

f. homogeneous

g. heterogeneous

h. homogeneous

53. **a.** Sodium chloride (table salt) is a compound because it is made of two elements, sodium and chloride.

b. Salt water is a mixture because it is made of two compounds, water (H_2O) and NaCl.

c. Sodium is an element because it is not combined with any other element.

57. The compound water contains two parts hydrogen to one part oxygen.

60. **a.** physical

b. chemical (color change)

c. chemical (production of a gas)

d. physical

62. 40 g NH_4NO_3 − 14 g N − 8 g O = 18 g H_2O

66. Sulfur, which is the only substance in the table that is a solid at room temperature

67. Mass is an extensive property, which depends only on the amount of matter in the sample, not on the composition of the sample.

70. The particles in solids are packed tightly together so it is difficult to compress them. The particles in a gas are spaced relatively far apart.

76. **a.** gas produced

b. formation of a precipitate

c. color and texture change

d. energy change, odor change

e. gas produced

f. color change, odor change

80. The wax appears to disappear because the products of the reaction—carbon dioxide and water vapor—are colorless gases.

81. Add sufficient water to dissolve all of the sugar. Separate the charcoal and sand from the sugar water by filtration. Large pieces of charcoal could be separated on the basis of color or size. Small pieces of charcoal could be burned.

85. **a.** Yes; because the graph is a straight line, the proportion of iron to oxygen is a constant, which is true for a compound.

b. No; a point for the values given wouldn't fall on the line. The mass ratio of iron to oxygen is different.

88. **a.** oxygen and calcium

b. silicon, aluminum, and iron

c. Different; the second most abundant element in Earth's crust, silicon, is not abundant in the human body, and the second most abundant element in the human body, carbon, is not among the most abundant elements in Earth's crust. If the elements are different, then the compounds must also be different.

Chapter 3

1. **a.** $(6.6 \times 10^{-8}) + (5.0 \times 10^{-9}) =$
$(6.6 \times 10^{-8}) + (0.5 \times 10^{-8}) =$
$(6.6 + 0.5) \times 10^{-8} = 7.1 \times 10^{-8}$

b. $(9.4 \times 10^{-2}) - (2.1 \times 10^{-2}) =$
$(9.4 - 2.1) \times 10^{-2} = 7.3 \times 10^{-2}$

2. $$\frac{6.6 \times 10^{6}}{(8.8 \times 10^{-2}) \times (2.5 \times 10^{3})} = 0.30 \times 10^{5} = 3.0 \times 10^{4}$$

R74 Appendix E

3. Error = experimental value − accepted value = 2.04 m − 2.00 m = 0.04 m

$$\%\ \text{error} = \frac{|\text{error}|}{\text{accepted value}} \times 100\% = \frac{|0.04\ \text{m}|}{2.00\ \text{m}} \times 100\% = 2\%$$

4. a. 4 b. 4 c. 2 d. 5

5. a. 3 b. 2 c. 4 d. 4

6. a. 8.71×10^{1} m
b. 4.36×10^{8} m
c. 1.55×10^{-2} m
d. 9.01×10^{3} m
e. 1.78×10^{-3} m
f. 6.30×10^{2} m

7. a. 9×10^{1} m
b. 4×10^{8} m
c. 2×10^{-2} m
d. 9×10^{3} m
e. 2×10^{-3} m
f. 6×10^{2} m

8. a. 61.2 m + 9.35 m + 8.6 m = 79.15 m = 79.2 m
b. 9.44 m − 2.11 m = 7.33 m
c. 1.36 m + 10.17 m = 11.53 m
d. 34.61m − 17.3 m = 17.3 m

9. 14.2 g + 8.73 g + 0.912 g = 23.842 g = 23.8 g

10. a. $8.3\ \text{m} \times 2.22\ \text{m} = 18.4\ \text{m}^2 = 18\ \text{m}^2 = 1.8 \times 10^{1}\ \text{m}^2$
b. $8432\ \text{m}^2 \div 12.5\ \text{m} = 675\ \text{m} = 6.75 \times 10^{2}$ m
c. $35.2\ \text{s} \times \frac{1\ \text{min}}{60\ \text{s}} = 0.587\ \text{min} = 5.87 \times 10^{-1}\ \text{min}$

11. $V = l \times w \times h = 22.4\ \text{m} \times 11.3\ \text{m} \times 5.2\ \text{m} = 1316.2\ \text{m}^3 = 1.3 \times 10^{3}\ \text{m}^3$

19. mp: K = °C + 273 = 960.8 + 273 = 1234 K
bp: K = °C + 273 = 2212 + 273 = 2485 K

20. °C = K − 273 = 77.2 − 273 = −196°C

21. $\text{Density} = \frac{\text{mass}}{\text{volume}} = \frac{612\ \text{g}}{245\ \text{cm}^3} = 2.50\ \text{g/cm}^3$

No, because the density of aluminum is 2.7 g/cm³

22. $\text{Density} = \frac{\text{mass}}{\text{volume}} = \frac{68.0\ \text{g}}{6.48\ \text{cm}^3} = 10.5\ \text{g/cm}^3$

36. $1\ \text{wk} \times \frac{7\ \text{d}}{1\ \text{wk}} \times \frac{24\ \text{h}}{1\ \text{d}} \times \frac{60\ \text{min}}{1\ \text{h}} = 10{,}080\ \text{min} = 1.0080 \times 10^{4}\ \text{min}$

37. $40\ \text{h} \times \frac{60\ \text{min}}{1\ \text{h}} \times \frac{60\ \text{s}}{1\ \text{min}} = 144{,}000\ \text{s} = 1.44000 \times 10^{5}\ \text{s}$

38. $570\ \text{cm ribbon} \times \frac{1\ \text{student}}{8.5\ \text{cm ribbon}} = 67\ \text{students}$

39. $48.0\ ^\circ\text{C change} \times \frac{1.80\ ^\circ\text{F change}}{1.00\ ^\circ\text{C change}} = 86.4\ ^\circ\text{F change}$

40. $5.00\ \text{g Au} \times \frac{1\ \text{atom Au}}{3.271 \times 10^{-22}\ \text{g Au}} = 1.53 \times 10^{22}\ \text{atoms Au}$

41. a. $0.044\ \text{km} \times \frac{10^{3}\ \text{m}}{1\ \text{km}} = 44\ \text{m}$

b. $4.6\ \text{mg} \times \frac{1\ \text{g}}{10^{3}\ \text{mg}} = 4.6 \times 10^{-3}\ \text{g}$

c. $0.107\ \text{g} \times \frac{10^{2}\ \text{cg}}{1\ \text{g}} = 10.7\ \text{cg}$

42. a. $15\ \text{cm}^3 \times \frac{1\ \text{L}}{10^{3}\ \text{cm}^3} = 0.015\ \text{L} = 1.5 \times 10^{-2}\ \text{L}$

b. $7.38\ \text{g} \times \frac{1\ \text{kg}}{10^{3}\ \text{g}} = 7.38 \times 10^{-3}\ \text{kg}$

c. $6.7\ \text{s} \times \frac{10^{3}\ \text{ms}}{1\ \text{s}} = 6.7 \times 10^{3}\ \text{ms}$

d. $94.5\ \text{g} \times \frac{10^{6}\ \mu\text{g}}{1\ \text{g}} = 9.45 \times 10^{7}\ \mu\text{g}$

43. a. $14.8\ \text{g B} \times \frac{1\ \text{cm}^3}{2.34\ \text{g B}} = 6.32\ \text{cm}^3$

b. $4.62\ \text{g Hg} \times \frac{1\ \text{cm}^3}{13.5\ \text{g Hg}} = 0.342\ \text{cm}^3 = 3.42 \times 10^{-1}\ \text{cm}^3$

44. a. $\text{Volume} = \frac{\text{mass}}{\text{density}} = \frac{14.8\ \text{g B}}{2.34\ \text{g B/cm}^3} = 6.32\ \text{cm}^3$

b. $\text{Volume} = \frac{\text{mass}}{\text{density}} = \frac{4.62\ \text{g Hg}}{13.5\ \text{g Hg/cm}^3} = 0.342\ \text{cm}^3 = 3.42 \times 10^{-1}\ \text{cm}^3$

45. $50.0\ \text{cm}^3 \times \frac{0.950\ \text{g}}{1\ \text{cm}^3} = 47.5\ \text{g}$

46. $0.227\ \text{nm} \times \frac{1\ \text{m}}{10^{9}\ \text{nm}} = 0.227 \times 10^{-9}\ \text{m} = 2.27 \times 10^{-8}\ \text{m}$

47. $1.3 \times 10^{4}\ \text{km} \times \frac{10^{3}\ \text{m}}{1\ \text{km}} \times \frac{10\ \text{dm}}{1\ \text{m}} = 1.3 \times 10^{4+3+1}\ \text{dm} = 1.3 \times 10^{8}\ \text{dm}$

48. $\frac{19.3\ \text{g}}{1\ \text{cm}^3} \times \frac{10^{6}\ \text{cm}^3}{1\ \text{m}^3} \times \frac{1\ \text{kg}}{10^{3}\ \text{g}} = 19.3 \times 10^{6-3}\ \text{kg/m}^3 = 19.3 \times 10^{3}\ \text{kg/m}^3 = 1.93 \times 10^{4}\ \text{kg/m}^3$

49. $\frac{7.0 \times 10^{6}\ \text{RBCs}}{1\ \text{mm}^3} \times \frac{10^{9}\ \text{mm}^3}{1\ \text{m}^3} \times \frac{1\ \text{m}^3}{10^{3}\ \text{dm}^3} \times \frac{1\ \text{dm}^3}{1\ \text{L}} = 7.0 \times 10^{6+9-3}\ \text{RBCs/L} = 7.0 \times 10^{12}\ \text{RBCs/L}$

59. a. 43 g

18. **a.** neutrons = mass number − atomic number = 80 − 35 = 45

b. neutrons = mass number − atomic number = 32 − 16 = 16

c. neutrons = mass number − atomic number = 108 − 47 = 61

d. neutrons = mass number − atomic number = 207 − 82 = 125

19. **a.** $^{12}_{6}C$ **b.** $^{11}_{5}B$ **c.** $^{9}_{4}Be$ **d.** $^{16}_{8}O$

20. $^{16}_{8}O$, $^{17}_{8}O$, $^{18}_{8}O$

21. neutrons = mass number − atomic number = 50 − 24 = 26; chromium-50 has 26 neutrons.

neutrons = mass number − atomic number = 52 − 24 = 28; chromium-52 has 28 neutrons.

neutrons = mass number − atomic number = 53 − 24 = 29; chromium-53 has 29 neutrons.

22. Boron's atomic mass (10.81 amu) is closer to 11 than it is to 10, so boron-11 is more abundant than boron-10.

23. Silicon's atomic mass (28.086 amu) is closest to 28 and closer to 29 than it is to 30. Therefore, silicon-28 is more abundant than silicon-29, and silicon-29 is more abundant than silicon-30.

24. for ^{63}Cu: 62.93 amu × 0.692 = 43.5 amu
for ^{65}Cu: 64.93 amu × 0.308 = 20.0 amu
atomic mass = 43.5 amu + 20.0 amu = 63.5 amu

25. for ^{79}Br: 78.92 amu × 0.5069 = 40.00 amu
for ^{81}Br: 80.92 amu × 0.4931 = 39.90 amu
atomic mass = 40.00 amu + 39.90 amu = 79.90 amu

40. repel

44. He did not expect alpha particles to be deflected at a large angle.

51. **a.** 19 **b.** 9 **c.** 14 **d.** 29
e. 22 **f.** 22 **g.** 25 **h.** 30

53. for ^{6}Li: 6.015 amu × 0.075 = 0.45 amu
for ^{7}Li: 7.016 amu × 0.925 = 6.49 amu
atomic mass = 0.45 amu + 6.49 amu = 6.94 amu

54. because of the existence of isotopes

60. 5 protons and 6 neutrons in the nucleus; 5 electrons outside the nucleus

64. [(82 + 122) × 0.014] + [(82 + 124) × 0.241] + [(82 + 125) × 0.221] + [(82 + 126) × 0.524] = 207 amu

66. **a.** 8,289,000 + 502,570 + 120,570 + 7800 + 1435 + 477 + 211 + 198 = 8,922,261

8,289,000 ÷ 8,922,261 = 0.929 = 92.9%

b. (8,289,000 + 502,570 + 120,570) ÷ 8,922,261 = 0.9989 = 99.89%

c. (477 + 211 + 198) ÷ 8,922,261 = 0.0000993 = 0.00993%

67. $^{14}_{7}$N: 14.003 amu; 99.63%
$^{15}_{7}$N: 15.000 amu; 0.37%
average atomic mass = 14.01 amu

74. The following are reasonable hypotheses: (*i*) The space in an individual atom is large relative to the volume of the atom but very small relative to an object the size of a hand. (*ii*) There are many layers of atoms in a wall or a desk. The space that exists is distributed evenly throughout the solid, similar to the distribution of air pockets in foam insulation.

78. $6.941 = [6.015 \times (1 - A)] + (7.016 \times A)$
$6.941 = 6.015 - 6.015A + 7.016A$
$6.941 - 6.015 = 7.016A - 6.015A$

$A = \frac{0.926}{1.001} = 0.925 = 92.5\%$

79. $17(1.67 \times 10^{-24}\ \text{g}) + 18(1.67 \times 10^{-24}\ \text{g}) + 17(9.11 \times 10^{-28}\ \text{g}) = 5.857 \times 10^{-23}\ \text{g}$
$5.857 \times 10^{-23}\ \text{g} - (5.81 \times 10^{-23}\ \text{g}) = 4.70 \times 10^{-25}\ \text{g}$

86. $54\ \text{g H}_2\text{O} - 6\ \text{g H} = 48\ \text{g O}$

42. **a.** 2 **b.** 3 **c.** 1 **d.** 6

44. **a.** $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^4$
b. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^2 4s^2$
c. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^3 4s^2$
d. $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2$

47. **a.** v, vi, iv, iii, i, ii
b. It is the reverse.

50. A quantum is a discrete amount of energy. Photons are light quanta.

51. A photon of ultraviolet light has a higher frequency (smaller wavelength) than a photon of infrared light. Therefore, a photon of ultraviolet light has more energy than a photon of infrared light.

52. $E = h\nu = (6.626 \times 10^{-34}\ \text{J}\cdot\text{s}) \times (5.80 \times 10^{14}/\text{s}) = 3.84 \times 10^{-19}\ \text{J}$

53. Classical physics views energy changes as continuous. In the quantum concept, energy changes occur in tiny discrete units called quanta.

54. The electron of the hydrogen atom is raised (excited) to a higher energy level.

57. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^3$; $n = 1$, 2 electrons; $n = 2$, 8 electrons; $n = 3$, 18 electrons; $n = 4$, 5 electrons; the fourth energy level ($n = 4$) is not filled.

59. $1s^2 2s^2 2p^3$; nitrogen (7 electrons); 3 unpaired electrons (in the 2*p* sublevel)

60. **a.** Na, sodium (11 electrons)
b. N, nitrogen (7 electrons)
c. Si, silicon (14 electrons)
d. O, oxygen (8 electrons)
e. K, potassium (19 electrons)
f. Ti, titanium (22 electrons)

63. **a.** $\lambda = 4.36 \times 10^{-7}\ \text{m} \times \frac{10^2\ \text{cm}}{1\ \text{m}} = 4.36 \times 10^{-5}\ \text{cm}$
b. ultraviolet

c. $\nu = \frac{c}{\lambda} = \frac{2.998 \times 10^8\ \text{m/s}}{4.36 \times 10^{-7}\ \text{m}} = 6.88 \times 10^{14}/\text{s}$

65. **a.** Electrons with a low velocity will be emitted.
b. More electrons will be emitted but with a low velocity.
c. Electrons will be emitted with a higher velocity.

66. $\nu = \frac{c}{\lambda} = \frac{2.998 \times 10^8\ \text{m/s}}{6.45 \times 10^{-7}\ \text{cm}} \times \frac{10^2\ \text{cm}}{1\ \text{m}}$
$= 4.65 \times 10^{14}/\text{s}$

$E = h\nu = (6.626 \times 10^{-34}\ \text{J}\cdot\text{s}) \times (4.65 \times 10^{14}/\text{s})$
$= 3.08 \times 10^{-19}\ \text{J}$

Red light is lower energy than green light.

69. **a.** emits energy
b. requires the absorption of energy
c. requires the absorption of energy
d. requires the absorption of energy

70. The outermost electron of sodium absorbs photons of wavelength 589 nm as it jumps to a higher energy level, but the electron is not energetic enough to emit a photon at this wavelength. Therefore, the white light spectrum exhibits a dark line at 589 nm.

72. **a.** $E = h\nu = h \times \frac{c}{\lambda} = 6.626 \times 10^{-34}\ \text{J}\cdot\text{s} \times \frac{2.998 \times 10^8\ \text{m/s}}{1.2 \times 10^{-4}\ \text{m}} = 1.7 \times 10^{-21}\ \text{J}$

b. $E = h\nu = h \times \frac{c}{\lambda} = 6.626 \times 10^{-34}\ \text{J}\cdot\text{s} \times \frac{2.998 \times 10^8\ \text{m/s}}{5.1 \times 10^{-7}\ \text{m}} = 3.9 \times 10^{-19}\ \text{J}$

R78 Appendix E

c. $E = h\nu = h \times \frac{c}{\lambda} = 6.626 \times 10^{-34}\ \text{J}\cdot\text{s} \times \frac{2.998 \times 10^{8}\ \cancel{\text{m}}/\cancel{\text{s}}}{1.4 \times 10^{-8}\ \cancel{\text{m}}} = 1.7 \times 10^{-17}\ \text{J}$

The energy of the photon of light increases as its wavelength decreases.

73. An orbit confines the electron to a fixed circular path around the nucleus; an orbital is a region around the nucleus in which electrons are likely to be found.

75. Answers will vary. Students may note that radio waves have the lowest energy in the electromagnetic spectrum and, thus, would not be energetic enough to cook food. Others may reason that if microwaves cook food faster than infrared radiation, then radio waves would cook food even faster.

78. **a.** atom with electron in $n = 1$ level

b. atom with electron in $n = 4$ level

c. atom with electron in $n = 4$ level

d. atom with electron in $n = 1$ level

79. The element is potassium (19 electrons).

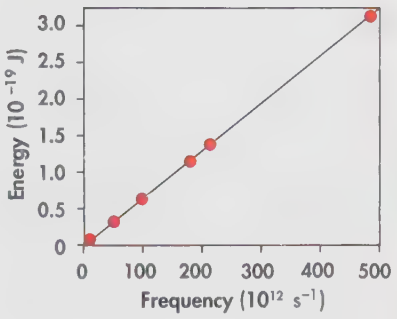
a. excited state, valence electron has been promoted from 4*s* to 5*p*

b. ground state, lowest energy electron configuration

c. impossible configuration, 3*p* orbitals can hold a maximum of 6 electrons, not 7

81. **a.** $\nu_1 = \frac{c}{\lambda} = \frac{2.998 \times 10^{8}\ \cancel{\text{m}}/\text{s}}{5.77 \times 10^{-3}\ \cancel{\text{cm}}} \times \frac{10^{2}\ \cancel{\text{cm}}}{1\ \cancel{\text{m}}} = 5.20 \times 10^{12}/\text{s}$

$\nu_2 = \frac{c}{\lambda} = \frac{2.998 \times 10^{8}\ \cancel{\text{m}}/\text{s}}{6.82 \times 10^{-4}\ \cancel{\text{cm}}} \times \frac{10^{2}\ \cancel{\text{cm}}}{1\ \cancel{\text{m}}} = 4.40 \times 10^{13}/\text{s}$



$\nu_3 = \frac{c}{\lambda} = \frac{2.998 \times 10^{8}\ \cancel{\text{m}}/\text{s}}{3.16 \times 10^{-4}\ \cancel{\text{cm}}} \times \frac{10^{2}\ \cancel{\text{cm}}}{1\ \cancel{\text{m}}} = 9.49 \times 10^{13}/\text{s}$

$\nu_4 = \frac{c}{\lambda} = \frac{2.998 \times 10^{8}\ \cancel{\text{m}}/\text{s}}{1.76 \times 10^{-4}\ \cancel{\text{cm}}} \times \frac{10^{2}\ \cancel{\text{cm}}}{1\ \cancel{\text{m}}} = 1.70 \times 10^{14}/\text{s}$

$\nu_5 = \frac{c}{\lambda} = \frac{2.998 \times 10^{8}\ \cancel{\text{m}}/\text{s}}{1.36 \times 10^{-4}\ \cancel{\text{cm}}} \times \frac{10^{2}\ \cancel{\text{cm}}}{1\ \cancel{\text{m}}} = 2.20 \times 10^{14}/\text{s}$

$\nu_6 = \frac{c}{\lambda} = \frac{2.998 \times 10^{8}\ \cancel{\text{m}}/\text{s}}{6.38 \times 10^{-5}\ \cancel{\text{cm}}} \times \frac{10^{2}\ \cancel{\text{cm}}}{1\ \cancel{\text{m}}} = 4.70 \times 10^{14}/\text{s}$

b.

c. $6.63 \times 10^{-34}\ \text{J}\cdot\text{s}$

d. The slope is Planck's constant.

83. Hydrogen atom ($Z = 1$), $n = 1$:

$$E = 1^2 \times \frac{2.18 \times 10^{-18}\ \text{J}}{1^2} = 2.18 \times 10^{-18}\ \text{J}$$

Hydrogen atom ($Z = 1$), $n = 2$:

$$E = 1^2 \times \frac{2.18 \times 10^{-18}\ \text{J}}{2^2} = 5.45 \times 10^{-19}\ \text{J}$$

Li^{2+} ion ($Z = 3$), $n = 1$:

$$E = 3^2 \times \frac{2.18 \times 10^{-18}\ \text{J}}{1^2} = 1.96 \times 10^{-17}\ \text{J}$$

85. Two magnets would push each other apart. In the same way, electrons with the same spin would push apart and be unable to occupy the same orbital.

88. The light emitted from an incandescent bulb has wavelengths from 300 nm to 700 nm, which corresponds to a frequency range of about $4 \times 10^{14}\ \text{s}^{-1}$ to $1 \times 10^{15}\ \text{s}^{-1}$:

$$\nu = \frac{c}{\lambda} = \frac{2.998 \times 10^{8}\ \cancel{\text{m}}/\text{s}}{700\ \cancel{\text{nm}}} \times \frac{10^{9}\ \cancel{\text{nm}}}{1\ \cancel{\text{m}}} = 4 \times 10^{14}\ \text{s}^{-1}$$

$$\nu = \frac{c}{\lambda} = \frac{2.998 \times 10^{8}\ \cancel{\text{m}}/\text{s}}{300\ \cancel{\text{nm}}} \times \frac{10^{9}\ \cancel{\text{nm}}}{1\ \cancel{\text{m}}} = 1 \times 10^{15}\ \text{s}^{-1}$$

This means that the energy absorbed by the photons is in the range of about 3×10^{-19} J to 7×10^{-19} J:

$E = h\nu = (6.626 \times 10^{-34}\ \text{J}\cdot\cancel{\text{s}}) \times (4 \times 10^{14}/\cancel{\text{s}}) = 3 \times 10^{-19}\ \text{J}$

$E = h\nu = (6.626 \times 10^{-34}\ \text{J}\cdot\cancel{\text{s}}) \times (1 \times 10^{15}/\cancel{\text{s}}) = 7 \times 10^{-19}\ \text{J}$

89. **a.** heterogeneous

b. heterogeneous

c. homogeneous

91. A compound has constant composition; the composition of a mixture can vary.

93. $77\ \text{pm} \times \frac{1\ \cancel{\text{m}}}{10^{12}\ \cancel{\text{pm}}} \times \frac{10^{6}\ \mu\text{m}}{1\ \cancel{\text{m}}} = 7.7 \times 10^{-5}\ \mu\text{m}$

Selected Solutions **R79**

95. mass of lead $= 28.0\,\cancel{cm^3} \times \dfrac{11.4\text{ g}}{1\,\cancel{cm^3}} = 319\text{ g}$

mass of gold $= 16.0\,\cancel{cm^3} \times \dfrac{19.3\text{ g}}{1\,\cancel{cm^3}} = 309\text{ g}$

The piece of lead has more mass.

97. **a.** exact **b.** exact **c.** not exact **d.** not exact

99. Volume of copper = 24.08 mL − 20.00 mL = 4.08 mL = 4.08 cm^3

$$\text{Density of copper} = \frac{\text{mass}}{\text{volume}} = \frac{36.4\text{ g}}{4.08\text{ cm}^3} = 8.92\text{ g/cm}^3$$

101. Helium gas is less dense than the nitrogen gas and oxygen gas in the air.

102. Accuracy is a measure of how close the value is to the true value; precision is a measure of how close a series of measurements are to one another.

105. Neon-20 has 10 neutrons in the nucleus; neon-21 has 11 neutrons in the nucleus.

Chapter 6

9. **a.** $1s^2 2s^2 2p^2$

b. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 5s^2$

c. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^3 4s^2$

10. **a.** B, Al, Ga, In, Tl

b. F, Cl, Br, I, At

c. Ti, Zr, Hf, Rf

27. The close match between the predicted properties and the actual properties of gallium helped gain wider acceptance for Mendeleev's periodic table.

34. helium

38. **a.** sodium **c.** germanium

b. strontium **d.** selenium

43. The ionic radius of a metal cation is smaller than the atomic radius of the metal atom.

47. **a.** O **b.** F **c.** O **d.** S

51. b; nitrogen and phosphorus are in the same group (Group 5A).

56. a. H, Li, Na, K, Rb, Cs, Fr

b. O, S, Se, Te, Po

c. Zn, Cd, Hg, Uub

60. It is relatively easy to remove two electrons from magnesium; it is much more difficult to remove a third electron. It is relatively easy to remove three electrons from aluminum; it is much more difficult to remove a fourth electron.

65. **a.** The electrons in calcium are removed from the same energy level. In potassium, the second electron is removed from a lower energy level.

b. Because cesium has a larger atomic radius than lithium, the nuclear charge in a cesium atom has a smaller effect on the electrons in the highest occupied energy level.

c. The third electron removed from a magnesium atom is in a lower energy level.

66. Zinc has a greater nuclear charge (more protons) than calcium.

68. **a.** $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6$

b. $1s^2 2s^2 2p^6$

c. $1s^2 2s^2 2p^6$

d. $1s^2 2s^2 2p^6$

75. Electron affinity increases (becomes more negative) from left to right across a period because the nuclear charge increases and the shielding effect is constant.

78. **a.** Possible cations are Rb^+ and Sr^{2+}; possible anions are Br^-, Se^{2-}, and As^{3-}.

b. No, a cation is isoelectronic with the noble gas in the preceding period, and an anion is isoelectronic with the noble gas in the same period.

85. **a.** physical change **c.** physical change

b. chemical change **d.** chemical change

90. **a.** $2.24\,\cancel{nm} \times \dfrac{1\text{ m}}{10^9\,\cancel{nm}} = 2.24 \times 10^{-9}\text{ m}$

b. $8.13\,\cancel{cm} \times \dfrac{1\text{ m}}{10^2\,\cancel{cm}} = 8.13 \times 10^{-2}\text{ m}$

c. $7.4\,\cancel{pm} \times \dfrac{1\text{ m}}{10^{12}\,\cancel{pm}} = 7.4 \times 10^{-12}\text{ m}$

d. $9.37\,\cancel{mm} \times \dfrac{1\text{ m}}{10^3\,\cancel{mm}} = 9.37 \times 10^{-3}\text{ m}$

93. The density of the olive is 1.05 g/cm^3. The olive will sink because its density is greater than that of water.

98. **a.** 48 **b.** 44 **c.** 114 **d.** 110

100. **a.** none **b.** one, 2*p* **c.** none **d.** nonet

Chapter 7

10. **a.** In order to have a completely filled valence shell, the iodine atom must gain 1 electron. This electron comes from 1 potassium atom, which loses 1 electron. The formula is KI.

b. Each oxygen atom needs 2 electrons to have an octet, but each aluminum atom loses 3 electrons; so, 2 aluminum atoms are needed for every 3 oxygen atoms. The formula is Al_2O_3.

11. A calcium atom loses 2 valence electrons to form a Ca^{2+} cation. A chlorine atom gains 1 electron to form a Cl^- anion. The formula of the compound that forms is $CaCl_2$.

R80 Appendix E

28. **a.** Group 5A; 5 valence electrons
b. Group 1A; 1 valence electron
c. Group 5A; 5 valence electrons
d. Group 2A; 2 valence electrons
e. Group 7A; 7 valence electrons
f. Group 4A; 4 valence electrons

31. **a.** 2; a calcium atom has 2 valence electrons, which it can lose.
b. 3; an aluminum atom has 3 valence electrons, which it can lose.
c. 1; a lithium atom has 1 valence electron, which it can lose.
d. 2; a barium atom has 2 valence electrons, which it can lose.

34. **a.** 3; a nitrogen atom has 5 valence electrons. It achieves an octet by gaining 3 electrons.
b. 2; a sulfur atom has 6 valence electrons. It achieves an octet by gaining 2 electrons.
c. 1; a chlorine atom has 7 valence electrons. It achieves an octet by gaining 1 electron.
d. 3; a phosphorus atom has 5 valence electrons. It achieves an octet by gaining 3 electrons.

35. **a.** A sulfur atom has 6 valence electrons and gains 2 electrons to attain a noble-gas configuration. The formula of the ion formed is S^{2-}.
b. A sodium atom has 1 valence electron and loses 1 electron to attain a noble-gas configuration. The formula of the ion formed is Na^{+}.
c. A fluorine atom has 7 valence electrons and gains 1 electron to attain a noble-gas configuration. The formula of the ion formed is F^{-}.
d. A phosphorus atom has 5 valence electrons and gains 3 electrons to attain a noble-gas configuration. The formula of the ion formed is P^{3-}.

40. a, c, e (ionic compounds form between atoms of metals and nonmetals)

43. **a.** Ca^{2+}, F^{-}
b. Al^{3+}, Br^{-}
c. Li^{+}, O^{2-}
d. Al^{3+}, S^{2-}
e. K^{+}, N^{3-}

47. Atoms in metals are arranged in a compact and orderly manner.

49. body-centered cubic: Na, K, Fe, Cr, or W; face-centered cubic: Cu, Ag, Au, Al, or Pb; hexagonal close-packed: Mg, Zn, or Cd

55. It has lost valence electrons.

58. **a.** sulfide ion (anion), S^{2-}
b. aluminum ion (cation), Al^{3+}
c. nitride ion (anion), N^{3-}
d. calcium ion (cation), Ca^{2+}

59. **a.** $1s^2\,2s^2\,2p^6\,3s^2\,3p^6\,3d^6$
b. $1s^2\,2s^2\,2p^6\,3s^2\,3p^6\,3d^7$
c. $1s^2\,2s^2\,2p^6\,3s^2\,3p^6\,3d^8$

62. All have the noble-gas configuration of $1s^2\,2s^2\,2p^6\,3s^2\,3p^6$.

67. a, c, e, f (these substances are not composed of metals and nonmetals)

68. **a.** $BaBr_2$ **b.** Al_2S_3 **c.** K_3N

72. 12

75. **a.** Cu, Zn
b. Ag, Cu
c. Cu, Sn
d. Fe, Cr, Ni, C

76. Each dot in the electron dot structure represents a valence electron in the electron configuration diagram.

79. **a.** 6A (the Ca^{2+} cation must be balanced by an anion with a charge of 2−)
b. 7A (the Mg^{2+} cation must be balanced by 2 anions with a charge of 1−)
c. 1A (the N^{3-} anion must be balanced by 3 cations with a charge of 1+)
d. 6A (the 2 Al^{3+} cations must be balanced by 3 anions with a charge of 2−)
e. 1A (the F^{-} anion must be balanced by a cation with a charge of 1+)
f. 2A (the S^{2-} anion must be balanced by a cation with a charge of 2+)

83. Both metals and ionic compounds are composed of ions. Both are held together by electrostatic attractions. Metals always conduct an electric current, and ionic compounds conduct an electric current only when melted or dissolved in water. Ionic compounds are composed of cations and anions, but metals are composed of cations and free-floating valence electrons. Metals are ductile, but ionic compounds are brittle.

86. **a.** Lithium is a metal; a lithium atom will form a cation by losing 1 electron.
b. Sodium is a metal; a sodium atom will form a cation by losing 1 electron.
c. Neon is a noble gas; it is chemically nonreactive.
d. Chlorine is a nonmetal; a chlorine atom will form an anion by gaining 1 electron.
e. Magnesium is a metal; a magnesium atom will form a cation by losing 2 electrons.

89. **a.** CaO; the electrostatic forces of attraction between the Ca^{2+} cations and O^{2-} anions in CaO are much stronger than the forces between the Na^{+} cations and Cl^{-} anions in NaCl.
b. Yes; CaO has stronger electrostatic attractions than NaCl, which must be overcome to melt the compound.

Selected Solutions **R81**

92. The charge on the copper cation is 2+. Its electron configuration is $1s^2\,2s^2\,2p^6\,3s^2\,3p^6\,3d^9$.

98. **a.** chemical **c.** physical
b. chemical **d.** chemical

100. **a.** liquid, vapor **c.** liquid, vapor
b. vapor **d.** liquid, vapor

102. **a.** $6 \times 10^4\ \text{cm} \times \dfrac{1\ \text{m}}{10^2\ \text{cm}} = 600\ \text{m}$

b. $6 \times 10^6\ \text{mm} \times \dfrac{1\ \text{m}}{10^3\ \text{mm}} = 6000\ \text{m}$

c. $0.06\ \text{km} \times \dfrac{10^3\ \text{m}}{1\ \text{km}} = 60\ \text{m}$

d. $6 \times 10^9\ \text{nm} \times \dfrac{1\ \text{m}}{10^9\ \text{nm}} = 6\ \text{m}$

Distance (b) is the longest.

104. $\text{volume} = \dfrac{\text{mass}}{\text{density}} = \dfrac{62.9\ \text{g}}{2.33\ \text{g/cm}^3} = 27.0\ \text{cm}^3$

108. **a.** 1 **b.** 3 **c.** 1 **d.** 5

111. **a.** $500\ \text{nm} \times \dfrac{1\ \text{m}}{10^9\ \text{nm}} = 5 \times 10^{-7}\ \text{m}$

b. ultraviolet

112. **a.** K, $1s^2\,2s^2\,2p^6\,3s^2\,3p^6\,4s^1$
b. Al, $1s^2\,2s^2\,2p^6\,3s^2\,3p^1$
c. S, $1s^2\,2s^2\,2p^6\,3s^2\,3p^4$
d. Ba, $1s^2\,2s^2\,2p^6\,3s^2\,3p^6\,3d^{10}\,4s^2\,4p^6\,4d^{10}\,5s^2\,5p^6\,6s^2$

Chapter 8

7. **a.** :Cl:Cl: **b.** :Br:Br: **c.** :I:I:

8. **a.** H:O:O:H **b.** :Cl:P:Cl: (:Cl: below P)

9. $[\text{H:O:}]^-$

10. $\left[\begin{array}{c}\text{:O:}\\ \text{:O:S:O:}\\ \text{:O:}\end{array}\right]^{2-}$ $\left[\begin{array}{c}\text{:O:}\\ \text{:O:C:}\\ \text{:O:}\end{array}\right]^{2-}$

29. **a.** 0.7; moderately polar covalent
b. 2.2; ionic
c. 1.0; moderately to very polar covalent
d. 1.0; moderately to very polar covalent
e. 2.5; ionic
f. 0; nonpolar covalent

30. c and d (tie at 0.4), b (0.7), a (0.9)

48. One atom contributes both electrons to a coordinate covalent bond, as in CO.

50. An unshared pair of electrons is needed for a coordinate covalent bond. There are no unshared pairs in compounds with only C—H and C—C bonds.

54. b and c; assuming only single bonds, the P and S atoms each have 10 valence electrons.

58. **a.** H:N:H (H below N) **b.** :Br:Cl: **c.** H:O:O:H **d.** H:Si:H (H above and below Si)

60. **a.** linear **d.** bent
b. tetrahedral **e.** linear
c. trigonal planar **f.** bent

63. **a.** sp^3 **b.** sp^2 **c.** sp **d.** sp

65. c (1.9), d (1.4), a (.09), f (0.5), b (0.4), e (0.0)

69. $1\ \text{mol CH}_4 \times \dfrac{393\ \text{kJ}}{1\ \text{mol CH}_4} \times 4 = 1572\ \text{kJ}$

71. The 3*s* and three 3*p* orbitals of phosphorus hybridize to form four sp^3 atomic orbitals. The resulting shape is pyramidal with a bond angle of 107° between the sigma bonds.

78. a (the phosphorus atom in PBr_5 has 10 valence electrons)

82. Ethyl alcohol can form intermolecular hydrogen bonds between its polar —OH groups, but dimethyl ether cannot form hydrogen bonds.

84. **a.** bent **b.** tetrahedral **c.** pyramidal

91. **a.** :F—Be—F: (Be has only 4 valence electrons.)

b.  (S has 12 valence electrons.)

c.  (Cl has only 7 valence electrons.)

d.  (B has only 6 valence electrons.)

e. :F—Xe—F: (Xe has 10 valence electrons.)

97. **a.** $66.5\ \text{mm} \times \dfrac{1\ \text{m}}{10^3\ \text{mm}} \times \dfrac{10^6\ \mu\text{m}}{1\ \text{m}} = 6.65 \times 10^4\ \mu\text{m}$

b. $4 \times 10^{-2}\ \text{g} \times \dfrac{100\ \text{cg}}{1\ \text{g}} = 4\ \text{cg}$

c. $\dfrac{5.62\ \text{mg}}{1\ \text{mL}} \times \dfrac{1\ \text{g}}{10^3\ \text{mg}} \times \dfrac{10\ \text{dg}}{1\ \text{g}} \times \dfrac{10^3\ \text{mL}}{1\ \text{L}} = 56.2\ \text{dg/L}$

d. $\dfrac{85\ \text{km}}{1\ \text{h}} \times \dfrac{1\ \text{h}}{60\ \text{min}} \times \dfrac{1\ \text{min}}{60\ \text{s}} \times \dfrac{10^3\ \text{m}}{1\ \text{km}} = 2.4 \times 10^1\ \text{m/s}$

101. Protons (positive charge) and electrons (negative charge) must be equal.

109. **a.** barium **b.** silicon **c.** sodium

R82 Appendix E

111. All have the same number of electrons as a noble gas.

Chapter 9

1. **a.** selenide ion **c.** phosphide ion
b. barium ion **d.** iodide ion

2. **a.** three electrons lost **c.** one electron lost
b. two electrons gained **d.** two electrons lost

10. **a.** BaS **b.** Li_2O **c.** Ca_3N_2 **d.** CuI_2

11. **a.** NaI **b.** $SnCl_2$ **c.** K_2S **d.** CaI_2

12. **a.** zinc sulfide **c.** barium oxide
b. potassium chloride **d.** copper(II) bromide

13. **a.** calcium oxide **c.** iron(II) sulfide
b. copper(I) selenide **d.** aluminum fluoride

14. **a.** $(NH_4)_2SO_3$ **b.** $Ca_3(PO_4)_2$

15. **a.** $LiHSO_4$ **b.** $Cr(NO_2)_3$

16. **a.** calcium oxalate
b. potassium hypochlorite
c. potassium permanganate
d. lithium sulfite

17. **a.** aluminum hydroxide **c.** tin(II) phosphate
b. sodium chlorate **d.** sodium chromate

27. **a.** oxygen difluoride **c.** sulfur trioxide
b. disulfur decafluoride **d.** sulfur hexafluoride

28. **a.** N_2O_4 **b.** XeF_4 **c.** S_2F_{10} **d.** IF_7

37. **a.** hydrofluoric acid
b. nitric acid
c. sulfurous acid

38. **a.** $HClO_4$ **b.** HI **c.** $HClO_2$

39. **a.** barium hydroxide
b. calcium hydroxide
c. rubidium hydroxide

40. **a.** CsOH **b.** $Be(OH)_2$ **c.** $Mn(OH)_3$

48. $\frac{2.98\text{ g Pb}}{0.461\text{ g O}} = \frac{x}{1.00\text{ g O}}$

$$x = \frac{2.98\text{ g Pb} \times 1.00\ \cancel{\text{g O}}}{0.461\ \cancel{\text{g O}}} = 6.46\text{ g Pb}$$

$$\frac{9.89\text{ g Pb}}{0.763\text{ g O}} = \frac{y}{1.00\text{ g O}}$$

$$y = \frac{9.89\text{ g Pb} \times 1.00\ \cancel{\text{g O}}}{0.763\ \cancel{\text{g O}}} = 13.0\text{ g Pb}$$

$$\text{mass ratio} = \frac{6.46\ \cancel{\text{g Pb}}}{13.0\ \cancel{\text{g Pb}}} = 1{:}2$$

49. Since $\frac{7\text{ Fe}}{3\text{ O}} = 2.3$ and $\frac{23\text{ g Fe}}{10\text{ g O}} = 2.3$, the compound must be iron(III) oxide.

58. **a.** 2+ **b.** 2+ **c.** 3+ **d.** 1+

64. Determine the charge of the anion, and then work the formula backward to find the charge of the transition metal cation needed to give a net charge of zero for the formula unit.

70. **a.** tri- **c.** di- **e.** penta-
b. mono- **d.** hexa- **f.** tetra-

76. **a.** lead(II) hydroxide **c.** $Cu(OH)_2$
b. cobalt(II) hydroxide **d.** $Fe(OH)_2$

79. No, the ratio of nitrogen to oxygen is 42:26, which is not a 7:4 ratio.

82. **a.** sodium chlorate
b. mercury(I) bromide
c. potassium chromate
d. perchloric acid
e. tin(IV) oxide
f. iron(III) acetate
g. potassium hydrogen sulfate
h. calcium hydroxide
i. barium sulfide

86. binary molecular compound

88. $SnCl_4$

96. **a.** N_2O, dinitrogen monoxide
b. NO_2, nitrogen dioxide
c. NO, nitrogen monoxide
d. N_2O_4, dinitrogen tetroxide

98. **a.** The charges do not balance; CsCl.
b. Neon does not form compounds.
c. The charges do not balance; ZnO.
d. The subscripts are not the lowest whole-number ratio; BaS.

100. binary ionic compounds: d and g; binary molecular compounds: a and f; compounds with polyatomic ions: b, c, e, h, and i; acids: b and e; base: c

101. **a.** 3.60 g solid/1.40 g gas = 2.57 and
6.48 g solid/2.52 g gas = 2.57
The compound obeys the law of definite proportions.
b. % gas = 1.40/5.00 and 2.52/9.00 = 28.0% gas
$0.28 \times 14.0\text{ g} = 3.92\text{ g}$ colorless gas

102. law of conservation of mass

Selected Solutions **R83**

106. **a.** Potassium carbonate has a greater water solubility than $CaCO_3$, so you could see which one dissolves in water more readily.

b. The copper compound is blue; the iron compound is white.

c. Add water to dissolve the NH_4Cl, and then filter out the insoluble $BaSO_4$.

d. chlorine (nonmetal), sulfur (nonmetal), bromine (nonmetal), barium (metal), iodine (nonmetal), mercury (metal)

e. barium sulfate, calcium carbonate, potassium carbonate, copper(II) sulfate pentahydrate, iron(II) sulfate pentahydrate, ammonium chloride

f. mass = density × volume

$\text{mass} = 47.0\ \cancel{\text{cm}^3} \times 13.59\ \text{g}/\cancel{\text{cm}^3} = 639\ \text{g Hg}$

g. $\text{volume} = \dfrac{\text{mass}}{\text{density}} = \dfrac{16.6\ \cancel{\text{g}}}{2.07\ \cancel{\text{g}}/\text{cm}^3} = 8.02\ \text{cm}^3$

h. color, density, melting point, and boiling point

111. ionic; $Ca(OH)_2$

113. **a.** 4 **b.** 2 **c.** 2 **d.** 4 **e.** 2 **f.** 1

118. **a.** 2 **b.** protons **c.** electrons **d.** neutrons

119. **a.** neon **b.** carbon **c.** boron **d.** helium

124. **a.** 1 **b.** 6 **c.** 8 **d.** 2 **e.** 7 **f.** 5

127. b and c; molecular compounds formed by two nonmetals have covalent bonds.

Chapter 10

1. $0.50\ \cancel{\text{bushel apples}} \times \dfrac{1\ \cancel{\text{dozen apples}}}{0.20\ \cancel{\text{bushel apples}}} \times \dfrac{2.0\ \text{kg apples}}{1\ \cancel{\text{dozen apples}}} = 5.0\ \text{kg apples}$

2. $14\ \cancel{\text{kg apples}} \times \dfrac{1\ \cancel{\text{dozen apples}}}{2.0\ \cancel{\text{kg apples}}} \times \dfrac{12\ \cancel{\text{apples}}}{1\ \cancel{\text{dozen apples}}} \times \dfrac{8\ \text{seeds}}{1\ \cancel{\text{apple}}} = 670\ \text{seeds}$

3. $2.80 \times 10^{24}\ \cancel{\text{atoms Si}} \times \dfrac{1\ \text{mol Si}}{6.02 \times 10^{23} \times \cancel{\text{atoms Si}}} = 4.65\ \text{mol Si}$

$2.17 \times 10^{23}\ \cancel{\text{molecules Br}_2} \times \dfrac{1\ \text{mol Br}_2}{6.02 \times 10^{23}\ \cancel{\text{molecules Br}_2}} = 0.360\ \text{mol Br}_2$

4. $2.12\ \cancel{\text{mol C}_3\text{H}_8} \times \dfrac{3\ \text{atoms C}}{1\ \cancel{\text{mol C}_3\text{H}_8}} = 6.36\ \text{atoms C}$

$2.12\ \cancel{\text{mol C}_3\text{H}_8} \times \dfrac{8\ \text{atoms H}}{1\ \cancel{\text{mol C}_3\text{H}_8}} = 17.0\ \text{atoms H}$

5. $1.14\ \cancel{\text{mol SO}_3} \times \dfrac{6.02 \times 10^{23}\ \cancel{\text{molecules SO}_3}}{1\ \cancel{\text{mol SO}_3}} \times \dfrac{3\ \text{atoms}}{1\ \cancel{\text{molecule SO}_3}} = 2.06 \times 10^{24}\ \text{atoms}$

6. $2.12\ \cancel{\text{mol C}_3\text{H}_8} \times \dfrac{6.02 \times 10^{23}\ \cancel{\text{molecules C}_3\text{H}_8}}{1\ \cancel{\text{mol C}_3\text{H}_8}} \times \dfrac{3\ \text{C atoms}}{1\ \cancel{\text{molecule C}_3\text{H}_8}} = 3.83 \times 10^{24}\ \text{C atoms}$

$2.12\ \cancel{\text{mol C}_3\text{H}_8} \times \dfrac{6.02 \times 10^{23}\ \cancel{\text{molecules C}_3\text{H}_8}}{1\ \cancel{\text{mol C}_3\text{H}_8}} \times \dfrac{8\ \text{H atoms}}{1\ \cancel{\text{molecule C}_3\text{H}_8}} = 1.02 \times 10^{25}\ \text{H atoms}$

7. $1\ \cancel{\text{mol P}} \times \dfrac{31.0\ \text{g P}}{1\ \cancel{\text{mol P}}} = 31.0\ \text{g P}$

$3\ \cancel{\text{mol Cl}} \times \dfrac{35.5\ \text{g Cl}}{1\ \cancel{\text{mol Cl}}} = 106.5\ \text{g Cl}$

mass of 1 mol PCl_3 = 31.0 g P + 106.5 g Cl = 138.0 g

molar mass of PCl_3 = 138 g/mol

8. $1\ \cancel{\text{mol Na}} \times \dfrac{23.0\ \text{g Na}}{1\ \cancel{\text{mol Na}}} = 23.0\ \text{g Na}$

$1\ \cancel{\text{mol H}} \times \dfrac{1.0\ \text{g H}}{1\ \cancel{\text{mol H}}} = 1.0\ \text{g H}$

$1\ \cancel{\text{mol C}} \times \dfrac{12.0\ \text{g C}}{1\ \cancel{\text{mol C}}} = 12.0\ \text{g C}$

$3\ \cancel{\text{mol O}} \times \dfrac{16.0\ \text{g O}}{1\ \cancel{\text{mol O}}} = 48.0\ \text{g O}$

mass of 1 mol $NaHCO_3$ = 23.0 g + 1.0 g + 12.0 g + 48.0 g = 84.0 g

molar mass of $NaHCO_3$ = 84.0 g/mol

16. $20\ \cancel{\text{mol C}} \times \dfrac{12.0\ \text{g C}}{1\ \cancel{\text{mol C}}} = 240.0\ \text{g C}$

$42\ \cancel{\text{mol H}} \times \dfrac{1.0\ \text{g H}}{1\ \cancel{\text{mol H}}} = 42.0\ \text{g H}$

$1\ \text{mol C}_{20}\text{H}_{42} = 240.0\ \text{g C} + 42.0\ \text{g H} = 282.0\ \text{g C}_{20}\text{H}_{42}$

$4.52 \times 10^{-3}\ \cancel{\text{mol C}_{20}\text{H}_{42}} \times \dfrac{282.0\ \text{g C}_{20}\text{H}_{42}}{1\ \cancel{\text{mol C}_{20}\text{H}_{42}}} = 1.27\ \text{g}$

17. $1\ \cancel{\text{mol Fe}} \times \dfrac{55.8\ \text{g Fe}}{1\ \cancel{\text{mol Fe}}} = 55.8\ \text{g Fe}$

$2\ \cancel{\text{mol O}} \times \dfrac{16.0\ \text{g O}}{1\ \cancel{\text{mol O}}} = 32.0\ \text{g O}$

$2\ \cancel{\text{mol H}} \times \dfrac{1.0\ \text{g H}}{1\ \cancel{\text{mol H}}} = 2.0\ \text{g H}$

$1\ \text{mol Fe(OH)}_2 = 55.8\ \text{g Fe} + 32.0\ \text{g O} + 2.0\ \text{g H} = 89.8\ \text{g Fe(OH)}_2$

$2.50\ \cancel{\text{mol Fe(OH)}_2} \times \dfrac{89.8\ \text{g}}{1\ \cancel{\text{mol Fe(OH)}_2}} = 225\ \text{g Fe(OH)}_2$

18. $3.70 \times 10^{-1}\ \cancel{\text{g B}} \times \dfrac{1\ \text{mol B}}{10.8\ \cancel{\text{g B}}} = 3.43 \times 10^{-2}\ \text{mol B}$

R84 Appendix E

19. $2\ \text{mol N} \times \frac{14.0\ \text{g N}}{1\ \text{mol N}} = 28\ \text{g N}$

$3\ \text{mol O} \times \frac{16.0\ \text{g O}}{1\ \text{mol O}} = 48.0\ \text{g O}$

$1\ \text{mol } N_2O_3 = 28\ \text{g N} + 48.0\ \text{g O} = 76.0\ \text{g } N_2O_3$

$75.0\ \text{g } N_2O_3 \times \frac{1\ \text{mol } N_2O_3}{76.0\ \text{g } N_2O_3} = 0.987\ \text{mol } N_2O_3$

20. a. $3.20 \times 10^{-3}\ \text{mol } CO_2 \times \frac{22.4\ \text{L } CO_2}{1\ \text{mol } CO_2} = 7.17 \times 10^{-2}\ \text{L } CO_2$

b. $3.70\ \text{mol } N_2 \times \frac{22.4\ \text{L } N_2}{1\ \text{mol } N_2} = 82.9\ \text{L } N_2$

c. $0.960\ \text{mol } CH_4 \times \frac{22.4\ \text{L } CH_4}{1\ \text{mol } CH_4} = 21.5\ \text{L } CH_4$

21. a. $67.2\ \text{L } SO_2 \times \frac{1\ \text{mol } SO_2}{22.4\ \text{L } SO_2} = 3.00\ \text{mol } SO_2$

b. $0.880\ \text{L He} \times \frac{1\ \text{mol He}}{22.4\ \text{L He}} = 0.039\ \text{mol He}$

c. $1.00 \times 10^3\ \text{L } C_2H_6 \times \frac{1\ \text{mol } C_2H_6}{22.4\ \text{L } C_2H_6} = 44.6\ \text{mol } C_2H_6$

22. $\frac{3.58\ \text{g}}{\text{L}} \times \frac{22.4\ \text{L}}{1\ \text{mol}} = 80.2\ \text{g/mol}$

23. molar mass of Kr = 83.8 g/mol

$\frac{83.8\ \text{g}}{1\ \text{mol Kr}} \times \frac{1\ \text{mol Kr}}{22.4\ \text{L}} = 3.74\ \text{g/L}$

33. mass of compound = 9.03 g + 3.48 g = 12.51 g

$$\%\,\text{Mg} = \frac{\text{mass of Mg}}{\text{mass of compound}} \times 100\% = \frac{9.03\ \text{g}}{12.51\ \text{g}} \times 100\% = 72.2\%\ \text{Mg}$$

$$\%\,\text{N} = \frac{\text{mass of N}}{\text{mass of compound}} \times 100\% = \frac{3.48\ \text{g}}{12.51\ \text{g}} \times 100\% = 27.8\%\ \text{N}$$

34. mass of oxygen = 14.2 g − 13.2 g = 1.0 g

$$\%\,\text{Hg} = \frac{\text{mass of Hg}}{\text{mass of compound}} \times 100\% = \frac{13.2\ \text{g}}{14.2\ \text{g}} \times 100\% = 93.0\%\ \text{Hg}$$

$$\%\,\text{O} = \frac{\text{mass of O}}{\text{mass of compound}} \times 100\% = \frac{1.0\ \text{g}}{14.2\ \text{g}} \times 100\% = 7.0\%\ \text{O}$$

35. a. mass of N in 1 mol NH_3 = 1 mol × 14.0 g/mol = 14.0 g

molar mass of NH_3 = 14.0 g + 3 × 1.0 g = 17.0 g

$$\%\,\text{N} = \frac{\text{mass of N in 1 mol } NH_3}{\text{molar mass of } NH_3} \times 100\% = \frac{14.0\ \text{g}}{17.0\ \text{g}} \times 100\% = 82.4\%\ \text{N}$$

b. mass of N in 1 mol NH_4NO_3 = 1 mol × 14.0 g/mol = 14.0 g

molar mass of NH_4NO_3 = 14.0 g + 4 × 1.0 g + 14.0 g + 3 × 16.0 g = 80.0 g

$$\%\,\text{N} = \frac{\text{mass of N in 1 mol } NH_4NO_3}{\text{molar mass of } NH_4NO_3} \times 100\% = \frac{28.0\ \text{g}}{80.0\ \text{g}} \times 100\% = 35.0\%\ \text{N}$$

36. a. mass of C in 1 mol C_2H_6 = 2 mol × 12.0 g/mol = 24.0 g

mass of H in 1 mol C_2H_6 = 6 mol × 1.0 g/mol = 6.0 g

molar mass of C_2H_6 = 24.0 g + 6.0 g = 30.0 g

$$\%\,\text{C} = \frac{\text{mass of C in 1 mol } C_2H_6}{\text{molar mass of } C_2H_6} \times 100\% = \frac{24.0\ \text{g}}{30.0\ \text{g}} \times 100\% = 80.0\%\ \text{C}$$

$$\%\,\text{H} = \frac{\text{mass of H in 1 mol } C_2H_6}{\text{molar mass of } C_2H_6} \times 100\% = \frac{6.0\ \text{g}}{30.0\ \text{g}} = 20.0\%\ \text{H}$$

b. mass of Na in 1 mol $NaHSO_4$ = 1 mol × 23.0 g/ mol = 23.0 g

mass of H in 1 mol $NaHSO_4$ = 1 mol × 1.0 g/ mol = 1.0 g

mass of S in 1 mol $NaHSO_4$ = 1 mol × 32.1 g/ mol = 32.1 g

mass of O in 1 mol $NaHSO_4$ = 4 mol × 16.0 g/ mol = 64.0 g

molar mass of $NaHSO_4$ = 23.0 g + 1.0 g + 32.1 g + 64.0 g = 120.1 g

$$\%\text{Na} = \frac{\text{mass of Na in 1 mol } NaHSO_4}{\text{molar mass of } NaHSO_4} \times 100\% = \frac{23.0\ \text{g}}{120.1\ \text{g}} = 19.2\%\ \text{Na}$$

$$\%\,\text{H} = \frac{\text{mass of H in 1 mol } NaHSO_4}{\text{molar mass of } NaHSO_4} \times 100\% = \frac{1.0\ \text{g}}{120.1\ \text{g}} = 0.80\%\ \text{H}$$

$$\%\,\text{S} = \frac{\text{mass of S in 1 mol } NaHSO_4}{\text{molar mass of } NaHSO_4} \times 100\% = \frac{32.1\ \text{g}}{120.1\ \text{g}} = 26.7\%\ \text{S}$$

$$\%\,\text{O} = \frac{\text{mass of O in 1 mol } NaHSO_4}{\text{molar mass of } NaHSO_4} \times 100\% = \frac{64.0\ \text{g}}{120.1\ \text{g}} = 53.3\%\ \text{O}$$

37. a. $125\ \text{g } NH_3 \times \frac{82.4\ \text{g N}}{100\ \text{g } NH_3} = 103\ \text{g N}$

b. $125\ \text{g } NH_4NO_3 \times \frac{35.0\ \text{g N}}{100\ \text{g } NH_4NO_3} = 43.8\ \text{g N}$

Selected Solutions **R85**

38. a. $350\ \text{g}\ \cancel{C_2H_6} \times \dfrac{2.0\ \text{g} \times 10^1\ \text{g H}}{100\ \text{g}\ \cancel{C_2H_6}} = 7.0 \times 10^1\ \text{g H}$

b. $20.2\ \text{g}\ \cancel{NaHSO_4} \times \dfrac{0.83\ \text{g H}}{100\ \text{g}\ \cancel{NaHSO_4}} = 0.17\ \text{g H}$

39. a. $94.1\ \text{g}\ \cancel{O} \times \dfrac{1\ \text{mol O}}{16.0\ \text{g}\ \cancel{O}} = 5.88\ \text{mol O}$

$5.9\ \text{g}\ \cancel{H} \times \dfrac{1\ \text{mol H}}{1.0\ \text{g}\ \cancel{H}} = 5.9\ \text{mol H}$

The mole ratio of O to H is $O_{5.88}H_{5.9}$

$\dfrac{5.88\ \text{mol O}}{5.88} = 1\ \text{mol O}$

$\dfrac{5.9\ \text{mol H}}{5.88} = 1\ \text{mol H}$

The mole ratio of O to H is OH.
The empirical formula is OH.

b. $67.6\ \text{g}\ \cancel{Hg} \times \dfrac{1\ \text{mol Hg}}{200.6\ \text{g}\ \cancel{Hg}} = 0.337\ \text{mol Hg}$

$10.8\ \text{g}\ \cancel{S} \times \dfrac{1\ \text{mol S}}{32.1\ \text{g}\ \cancel{S}} = 0.336\ \text{mol S}$

$21.6\ \text{g}\ \cancel{O} \times \dfrac{1\ \text{mol O}}{16.0\ \text{g}\ \cancel{O}} = 1.35\ \text{mol O}$

The mole ratio of Hg to S to O is $Hg_{0.337}S_{0.336}O_{1.35}$.

$\dfrac{0.337\ \text{mol Hg}}{0.336} = 1\ \text{mol Hg}$

$\dfrac{0.336\ \text{mol S}}{0.336} = 1\ \text{mol S}$

$\dfrac{1.35\ \text{mol O}}{0.336} = 4\ \text{mol O}$

The mole ratio of Hg to S to O is $HgSO_4$.
The empirical formula is $HgSO_4$.

40. $62.1\ \text{g}\ \cancel{C} \times \dfrac{1\ \text{mol C}}{12.0\ \text{g}\ \cancel{C}} = 5.18\ \text{mol C}$

$13.8\ \text{g}\ \cancel{H} \times \dfrac{1\ \text{mol H}}{1.0\ \text{g}\ \cancel{H}} = 13.8\ \text{mol H}$

$24.1\ \text{g}\ \cancel{N} \times \dfrac{1\ \text{mol N}}{14.0\ \text{g}\ \cancel{N}} = 1.72\ \text{mol N}$

$\dfrac{5.18\ \text{mol C}}{1.72} = 3\ \text{mol C}$

$\dfrac{13.8\ \text{mol H}}{1.72} = 8\ \text{mol H}$

$\dfrac{1.72\ \text{mol N}}{1.72} = 1\ \text{mol N}$

The empirical formula is C_3H_8N.

41. efm of CClN = 12.0 g/mol + 35.5 g/mol + 14.0 g/mol = 61.5 g/mol

$\dfrac{\text{molar mass}}{\text{efm}} = \dfrac{184.5\ \text{g/}\cancel{\text{mol}}}{61.5\ \text{g/}\cancel{\text{mol}}} = 3$

$(CClN) \times 3 = C_3Cl_3N_3$.

42. efm = 12.0 g/mol + 3(1.0 g/mol) + 16.0 g/mol = 31.0 g/mol

$\dfrac{\text{molar mass}}{\text{efm of } CH_3O} = \dfrac{62.0\ \text{g/}\cancel{\text{mol}}}{31.0\ \text{g/}\cancel{\text{mol}}} = 2$

$(CH_3O) \times 2 = C_2H_6O_2$

51. a. molecule

c. $2.00\ \text{mol}\ C_{12}H_{22}O_{11} \times$

$$\frac{6.02 \times 10^{23}\ \text{molecules}\ C_{12}H_{22}O_{11}}{1\ \text{mol}\ C_{12}H_{22}O_{11}} \times \frac{22\ \text{H atoms}}{1\ \text{molecule}\ C_{12}H_{22}O_{11}} = 2.65 \times 10^{25}\ \text{H atoms}$$

d. $3.65\ \text{mol}\ C_{12}H_{22}O_{11} \times$

$$\frac{6.02 \times 10^{23}\ \text{molecules}\ C_{12}H_{22}O_{11}}{1\ \text{mol}\ C_{12}H_{22}O_{11}} \times \frac{11\ \text{O atoms}}{1\ \text{molecule}\ C_{12}H_{22}O_{11}} = 2.42 \times 10^{25}\ \text{O atoms}$$

82. **a.** efm of CH_2O = 12.0 g/mol + 2 × (1.0 g/mol) + 16.0 g/mol = 30.0 g/mol

Compound A: $\frac{\text{molar mass of A}}{\text{efm}} = \frac{60.0\ \text{g/mol}}{30.0\ \text{g/mol}} = 2$

$(CH_2O) \times 2 = C_2H_4O_2$

Compound D: $\frac{\text{molar mass of D}}{\text{efm}} = \frac{150.0\ \text{g/mol}}{30.0\ \text{g/mol}} = 5$

$(CH_2O) \times 5 = C_5H_{10}O_5$

Compound E: $\frac{\text{molar mass of E}}{\text{efm}} = \frac{180.0\ \text{g/mol}}{30.0\ \text{g/mol}} = 6$

$(CH_2O) \times 6 = C_6H_{12}O_6$

b. $\text{slope} = \frac{\Delta\ \text{molar mass}}{\Delta\ \text{mass of C}} = \frac{150.0 - 60.0}{60.0 - 24.0} = \frac{2.5}{1}$

The slope is the ratio of the empirical formula mass to the mass of carbon in the empirical formula: 30.0 g/12.0 g = 2.5/1.

c. The two other data points occur when molar mass/efm = 3 and 4. These data points correspond to compounds with molecular formulas $C_3H_6O_3$ and $C_4H_8O_4$, respectively. Thus, the *x*, *y* values are (36, 90) and (48, 120).

85. $90.0\ \text{g}\ Cl_2O \times \frac{1\ \text{mol}\ Cl_2O}{87.0\ \text{g}\ Cl_2O} \times \frac{1\ \text{mol O}}{1\ \text{mol}\ Cl_2O} \times \frac{16.0\ \text{g O}}{1\ \text{mol O}} = 16.6\ \text{g O}$

molar mass of Cl_2O = 2 × (35.5 g/mol) + 16.0 g/mol = 87.0 g/mol

$$90.0\ \text{g}\ Cl_2O \times \frac{1\ \text{mol}\ Cl_2O}{87.0\ \text{g}\ Cl_2O} \times \frac{16\ \text{mol O}}{87.0\ \text{mol}\ Cl_2O} \times \frac{16.0\ \text{g O}}{1\ \text{mol O}} = 3.05\ \text{g O}$$

87. $150.0\ \text{mg}\ C_{17}H_{18}FN_3O_3 \times$

$$\frac{1\ \text{g}\ C_{17}H_{18}FN_3O_3}{1000\ \text{mg}\ C_{17}H_{18}FN_3O_3} \times \frac{1\ \text{mol}\ C_{17}H_{18}FN_3O_3}{331.0\ \text{g}\ C_{17}H_{18}FN_3O_3} \times \frac{6.02 \times 10^{23}\ \text{molecules}\ C_{17}H_{18}FN_3O_3}{1\ \text{mol}\ C_{17}H_{18}FN_3O_3} \times \frac{1\ \text{F atom}}{1\ \text{molecule}\ C_{17}H_{18}FN_3O_3} = 2.73 \times 10^{20}\ \text{F atoms}$$

89. **a.** $94.1\ \text{g O} \times \frac{1\ \text{mol O}}{16.0\ \text{g O}} = 5.88\ \text{mol O}$

$5.9\ \text{g H} \times \frac{1\ \text{mol H}}{1.0\ \text{g H}} = 5.9\ \text{mol H}$

$\frac{5.88\ \text{mol O}}{5.88} = 1.00\ \text{mol O}$; $\frac{5.9\ \text{mol H}}{5.88} = 1.00\ \text{mol H}$;

The empirical formula is HO.

$$\frac{\text{molar mass}}{\text{efm}} = \frac{34\ \text{g/mol}}{17.0\ \text{g/mol}} = 2$$

$(HO) \times 2 = H_2O_2$

b. $50.7\ \text{g C} \times \frac{1\ \text{mol C}}{12.0\ \text{g C}} = 4.23\ \text{mol C}$

$4.2\ \text{g H} \times \frac{1\ \text{mol H}}{1.0\ \text{g H}} = 4.2\ \text{mol H}$

$45.1\ \text{g O} \times \frac{1\ \text{mol O}}{16.0\ \text{g O}} = 2.83\ \text{mol O}$

$\frac{4.23\ \text{mol C}}{2.83} = 1.49\ \text{mol C}$; $\frac{4.2\ \text{mol H}}{2.83} = 1.5\ \text{mol H}$;

$\frac{2.83\ \text{mol O}}{2.83} = 1.00\ \text{mol O}$

1.49 mol C × 2 = 3 mol C; 1.5 mol H × 2 = 3 mol H; 1.00 mol O × 2 = 2 mol O. The empirical formula is $C_3H_3O_2$.

R88 Appendix E

$$\frac{\text{molar mass}}{\text{efm}} = \frac{142\ \text{g/mol}}{71.0\ \text{g/mol}} = 2$$

$(C_3H_3O_2) \times 2 = C_6H_6O_4$

c. $56.6\ \text{g K} \times \frac{1\ \text{mol K}}{39.1\ \text{g K}} = 1.45\ \text{mol K}$

$8.7\ \text{g C} \times \frac{1\ \text{mol C}}{12.0\ \text{g C}} = 0.73\ \text{mol C}$

$34.7\ \text{g O} \times \frac{1\ \text{mol O}}{16.0\ \text{g O}} = 2.17\ \text{mol O}$

$\frac{1.45\ \text{mol K}}{0.73} = 2.00\ \text{mol K}$; $\frac{0.73\ \text{mol C}}{0.73} = 1.00\ \text{mol C}$;

$\frac{2.17\ \text{mol O}}{0.73} = 3.00\ \text{mol O}$

The empirical formula is K_2CO_3.

$$\frac{\text{molar mass}}{\text{efm}} = \frac{138.2\ \text{g/mol}}{138.2\ \text{g/mol}} = 1$$

$(K_2CO_3) \times 1 = K_2CO_3$

90. **a.** Atomic mass of boron = 10.8 amu

$15\ \text{atoms B} \times \frac{10.8\ \text{amu}}{1\ \text{atom B}} = 162\ \text{amu}$

$\frac{162\ \text{amu}}{6} = 27.0\ \text{amu}$

b. aluminum

91. $6.02 \times 10^{23}\ \text{particles} \times \frac{5 \times 10^{-6}\ \text{cm}}{1\ \text{particle}} \times \frac{1\ \text{m}}{100\ \text{cm}} \times \frac{1\ \text{km}}{1000\ \text{m}} = 3 \times 10^{13}\ \text{km}$

94. $5.50\ \text{L} \times \frac{1\ \text{mol He}}{22.4\ \text{L}} \times \frac{4.0\ \text{g He}}{1\ \text{mol He}} = 0.98\ \text{g He}$

96. Let the number of carbon atoms = x. Then, the empirical formula is $C_xH_{3x}O_{x/2}$. The smallest value of x that will give whole number subscripts is 2. Therefore, the empirical formula is C_2H_6O.

100. **a.** $68\ \text{g C} \times \frac{1\ \text{mol C}}{12.0\ \text{g C}} = 5.7\ \text{mol C}$

$7\ \text{g H} \times \frac{1\ \text{mol H}}{1.0\ \text{g H}} = 7.0\ \text{mol H}$

$20\ \text{g O} \times \frac{1\ \text{mol O}}{16.0\ \text{g O}} = 1.3\ \text{mol O}$

$9\ \text{g N} \times \frac{1\ \text{mol N}}{14.0\ \text{g N}} = 0.64\ \text{mol N}$

$\frac{5.7\ \text{mol C}}{0.64} = 9\ \text{mol C}$; $\frac{7\ \text{mol H}}{0.64} = 11\ \text{mol H}$;

$\frac{1.3\ \text{mol O}}{0.64} = 2\ \text{mol O}$; $\frac{0.6\ \text{mol N}}{0.64} = 1\ \text{mol N}$

The empirical formula is $C_9H_{11}O_2N$.

b. $\frac{\text{molar mass}}{\text{efm}} = \frac{165.2\ \text{g/mol}}{165.0\ \text{g/mol}} = 1$

The molecular formula is $C_9H_{11}O_2N$.

101. From the given information, the ratio of atoms is $C_{0.6}H_1O_{1.8}N_{0.6}$. The empirical formula is $(C_{0.6}H_1O_{1.8}N_{0.6}) \times 5 = C_3H_5O_9N_3$.

efm = 3 × (12.0 g/mol) + 5 × (1.0 g/mol) + 9 × (16.0 g/mol) + 3 × (14.0 g/mol) = 227.0 g/mol

$\text{molar mass} = \frac{1.00\ \text{g}}{0.00441\ \text{mol}} = 227\ \text{g/mol}$

$\frac{\text{molar mass}}{\text{efm}} = \frac{227}{227.0} = 1$

The molecular formula is also $C_3H_5O_9N_3$.

103. $75.0\ \text{g air} \times \frac{1\ \text{L air}}{1.19\ \text{g air}} \times \frac{20.95\ \text{L O}_2}{100\ \text{L air}} \times \frac{1\ \text{mol O}_2}{22.4\ \text{L O}_2} \times \frac{6.02 \times 10^{23}\ \text{molecules O}_2}{1\ \text{mol O}_2} = 3.54 \times 10^{23}\ \text{molecules O}_2$

105. Consider a cube containing 1 mol of NaCl. The mass of the cube (to 4 significant figures) would then be 22.99 g + 35.45 g = 58.44 g. The volume of the cube can be calculated using the density of solid NaCl:

$58.44\ \text{g NaCl} \times \frac{1\ \text{cm}^3}{2.165\ \text{g NaCl}} = 26.99\ \text{cm}^3$

The length of one side of the cube is then

$\sqrt[3]{26.99\ \text{cm}^3} = 3.000\ \text{cm}$

The number of ions per side is as follows:

$3.000\ \text{cm} \times \frac{1\ \text{ion}}{2.819 \times 10^{-8}\ \text{cm}} = 1.064 \times 10^8\ \text{ions}$

The total number of ions in the cube is then $(1.064 \times 10^8\ \text{ions})^3 = 1.205 \times 10^{24}\ \text{ions}$

To calculate Avogadro's number, determine the number of formula units in the cube:

$1.205 \times 10^{24}\ \text{ions} \times \frac{1\ \text{formula unit}}{2\ \text{ions}} =$

$6.025 \times 10^{23}\ \text{formula units}$

108. $30.0\ \text{mg} \times \frac{1\ \text{g}}{1000\ \text{mg}} \times \frac{1\ \text{mol of compound}}{312\ \text{g}} \times \frac{6.02 \times 10^{23}\ \text{molecules}}{1\ \text{mol of compound}} = 5.79 \times 10^{19}\ \text{molecules}$

116. a. 40 protons, 40 electrons, 50 neutrons

b. 46 protons, 46 electrons, 62 neutrons

c. 35 protons, 35 electrons, 46 neutrons

d. 51 protons, 51 electrons, 72 neutrons

117. a. $1s^2 2s^2 2p^5$

b. $1s^2 2s^1$

c. $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 5s^1$

119. Cr, Cd, Cu, Co

126. d. CaS_2 f. Ba(OH)

127. a. iron(III) hydroxide c. sodium carbonate

b. ammonium iodide d. carbon tetrachloride

128. a. KNO_3 b. CuO c. Mg_3N_2 d. AgF

Chapter 11

1. When solid sodium is dropped in water, hydrogen gas and aqueous sodium hydroxide are produced.

2. $S(s) + O_2(g) \longrightarrow SO_2(g)$

3. $3CO + Fe_2O_3 \longrightarrow 2Fe + 3CO_2$

4. $2C + O_2 \longrightarrow 2CO$

5. a. $FeCl_3 + 3NaOH \longrightarrow Fe(OH)_3 + 3NaCl$

b. $CS_2 + 3Cl_2 \longrightarrow CCl_4 + S_2Cl_2$

c. $2KI + Pb(NO_3)_2 \longrightarrow PbI_2 + 2KNO_3$

d. $2C_2H_2 + 5O_2 \longrightarrow 4CO_2 + 2H_2O$

6. a. $Ca(OH)_2 + H_2SO_4 \longrightarrow CaSO_4 + 2H_2O$

b. $Na + H_2O \longrightarrow NaOH + H$

12. HBr

13. $2HI \longrightarrow H_2 + I_2$

14. $3Mg + N_2 \longrightarrow Mg_3N_2$

15. a. $Fe(s) + Pb(NO_3)_2(aq) \longrightarrow Fe(NO_3)_2(aq) + Pb(s)$

b. $Cl_2(aq) + 2NaI(aq) \longrightarrow 2NaCl(aq) + I_2(aq)$

c. $Ca(s) + 2H_2O(l) \longrightarrow Ca(OH)_2(aq) + H_2(g)$

d. $Zn(s) + H_2SO_4(aq) \longrightarrow ZnSO_4(aq) + H_2(g)$

16. a. $3NaOH(aq) + Fe(NO_3)_3(aq) \longrightarrow Fe(OH)_3(s) + 3NaNO_3(aq)$

b. $3Ba(NO_3)_2(aq) + 2H_3PO_4(aq) \longrightarrow Ba_3(PO_4)_2(s) + 6HNO_3(aq)$

c. $FeS(s) + 2HCl(aq) \longrightarrow H_2S(g) + FeCl_2(aq)$

17. a. $3KOH(aq) + H_3PO_4(aq) \longrightarrow K_3PO_4(aq) + 3H_2O(l)$

b. $AgNO_3(aq) + NaCl(s) \longrightarrow AgCl(s) + NaNO_3(aq)$

c. $3Ca(OH)_2(aq) + 2H_3PO_4(aq) \longrightarrow Ca_3(PO_4)_2(aq) + 6H_2O(l)$

d. $2KI(aq) + Pb(NO_3)_2(aq) \longrightarrow 2KNO_3(aq) + PbI_2(s)$

e. $3H_2SO_4(aq) + 2Al(OH)_3(aq) \longrightarrow Al_2(SO_4)_3(aq) + 6H_2O(l)$

18. a. $CH_2O(g) + O_2(g) \longrightarrow CO_2(g) + H_2O(g)$

b. $C_7H_{16}(l) + 11O_2(g) \longrightarrow 7CO_2(g) + 8H_2O(g)$

c. $2C_6H_6(l) + 15O_2(g) \longrightarrow 12CO_2(g) + 6H_2O(g)$

19. a. $C_6H_{12}O_6(s) + 6O_2(g) \longrightarrow 6CO_2(g) + 6H_2O(g)$

b. $C_3H_6O(l) + 4O_2(g) \longrightarrow 3CO_2(g) + 3H_2O(g)$

c. $2C_5H_{12}O(l) + 15O_2(g) \longrightarrow 10CO_2(g) + 12H_2O(g)$

25. $OH^-(aq) + H^+(aq) \longrightarrow H_2O(l)$

26. Complete ionic equation:
$3Ca^{2+}(aq) + 6OH^-(aq) + 6H^+(aq) + 2PO_4^{3-}(aq) \longrightarrow Ca_3(PO_4)_2(s) + 6H_2O(l)$

Net ionic equation: same as complete ionic equation

27. The precipitate formed is lead chloride.
$Pb^{2+}(aq) + Cl^-(aq) \longrightarrow PbCl_2(s)$

28. Complete ionic equation:
$Fe^{3+}(aq) + NO^{3-}(aq) + 3Na^+(aq) + 3OH^-(aq) \longrightarrow 3Na^+(aq) + NO^{3-}(aq) + Fe(OH)_3(s)$

Net ionic equation:
$Fe^{3+}(aq) + OH^-(aq) \longrightarrow Fe(OH)_3(s)$

37. a. $2PbO_2(s) \longrightarrow 2PbO(s) + O_2(g)$

b. $2Fe(OH)_3(s) \longrightarrow Fe_2O_3(s) + 3H_2O(l)$

c. $(NH_4)_2CO_3(s) \longrightarrow 2NH_3(g) + H_2O(g) + CO_2(g)$

d. $CaCl_2(aq) + H_2SO_4(aq) \longrightarrow CaSO_4(s) + 2HCl(aq)$

38. a. $2Mg(s) + O_2(g) \longrightarrow 2MgO(s)$

b. $4P(s) + 5O_2(g) \longrightarrow 2P_2O_5(s)$

c. $Ca(s) + S(s) \longrightarrow CaS(s)$

46. a. $H^+(aq) + OH^-(aq) \longrightarrow H_2O(l)$

b. $Ag^+(aq) + Cl^-(aq) \longrightarrow AgCl(s)$

51. a. $Na_2O(s) + H_2O(l) \longrightarrow 2NaOH(aq)$

b. $H_2(g) + Br_2(g) \longrightarrow 2HBr(g)$

c. $Cl_2O_7(l) + H_2O(l) \longrightarrow 2HClO_4(aq)$

R90 Appendix E

53. a. tube A

b. $2Na(s) + 2H_2O(l) \longrightarrow 2NaOH(aq) + H_2(g)$
single-replacement

57. a. $CdS(s)$

b. $Na^+(aq)$ and $NO_3^-(aq)$

c. $Cd^{2+}(aq) + S^{2-}(aq) \longrightarrow CdS(s)$

60. a. single-replacement

b. $Cl_2(g) + 2I^-(aq) \longrightarrow I_2(aq) + 2Cl^-(aq)$

62. a. $2K(s) + 2H_2O(l) \longrightarrow 2KOH(aq) + H_2(g)$

b. $C_2H_5OH(l) + 3O_2(g) \longrightarrow 2CO_2(g) + 3H_2O(g)$

c. $2Bi(NO_3)_3(aq) + 3H_2S(g) \longrightarrow Bi_2S_3(s) + 6HNO_3(aq)$

d. $2Al(s) + 3Br_2(l) \longrightarrow 2AlBr_3(s)$

65. Smoking is not permitted near an oxygen source because a fire will burn faster in an area of high oxygen concentration. However, if a match were struck in a room full of oxygen and isolated from combustible material, it would only burn more vigorously.

70. 22 protons, 28 neutrons, and 22 electrons

74. a. K_2CrO_4 c. permanganic acid

b. $NaHSO_3$ d. potassium oxalate

77. First, determine the empirical formula.

$$49.5 \text{ g-C} \times \frac{1 \text{ mol C}}{12.0 \text{ g-C}} = 4.13 \text{ mol C}$$

$$5.20 \text{ g-H} \times \frac{1 \text{ mol H}}{1.01 \text{ g-H}} = 5.15 \text{ mol H}$$

$$16.5 \text{ g-O} \times \frac{1 \text{ mol O}}{16.0 \text{ g-O}} = 1.03 \text{ mol O}$$

$$28.9 \text{ g-N} \times \frac{1 \text{ mol N}}{14.0 \text{ g-N}} = 2.06 \text{ mol N}$$

Then, divide each value by 1.03. The empirical formula is $C_4H_5ON_2$. The mass of the empirical formula is 97 g.

$$\frac{\text{gfm}}{\text{efm}} = \frac{194.1 \text{ g}}{97 \text{ g}} = 2$$

$(C_4H_5ON_2) \times 2 = C_8H_{10}O_2N_4$

Chapter 12

1. $288 \text{ ESW}_3\text{HP}_2 \times \frac{1 \text{ seat}}{1 \text{ ESW}_3\text{HP}_2} = 288 \text{ seats}$

$$288 \text{ ESW}_3\text{HP}_2 \times \frac{3 \text{ wheels}}{1 \text{ ESW}_3\text{HP}_2} = 864 \text{ wheels}$$

$$288 \text{ ESW}_3\text{HP}_2 \times \frac{2 \text{ pedals}}{1 \text{ ESW}_3\text{HP}_2} = 576 \text{ pedals}$$

2. Answers will vary but should include the correct number of "parts" to make the product. For example, 1 deck + 2 trucks + 4 wheels $\longrightarrow DT_2W_4$. Note: The truck (T) of a skateboard holds the wheels (W). The deck (D) of a skateboard is the part that a skateboarder stands on when riding.

3. 2 molecules H_2 + 1 molecule $O_2 \longrightarrow$ 2 molecules H_2O

2 moles H_2 + 1 mole $O_2 \longrightarrow$ 2 moles H_2O

44.8 L H_2 + 22.4 L $O_2 \longrightarrow$ 44.8 L H_2O

4. $C_2H_4(g) + 3O_2 \longrightarrow 2CO_2(g) + 2H_2O(g)$;

1 mol C_2H_4 + 3 mol $O_2 \longrightarrow$ 2 mol CO_2 + 2 mol H_2O;

22.4 L C_2H_4 + 67.2 L $O_2 \longrightarrow$ 44.8 L CO_2 + 44.8 L H_2O;

$$\left(1 \text{ mol} \times \frac{28.0 \text{ g}}{\text{mol}}\right) + \left(3 \text{ mol} \times \frac{32.0 \text{ g}}{\text{mol}}\right) \longrightarrow \left(2 \text{ mol} \times \frac{44.0 \text{ g}}{\text{mol}}\right) + \left(2 \text{ mol} \times \frac{18.0 \text{ g}}{\text{mol}}\right)$$

28.0 g C_2H_4 + 96.0 g $O_2 \longrightarrow$ 88.0 g CO_2 + 36.0 g H_2O

124 g = 124 g

11. a. $\frac{4 \text{ mol Al}}{3 \text{ mol O}_2}$ $\frac{3 \text{ mol O}_2}{4 \text{ mol Al}}$ $\frac{4 \text{ mol Al}}{2 \text{ mol Al}_2\text{O}_3}$

$\frac{2 \text{ mol Al}_2\text{O}_3}{4 \text{ mol Al}}$ $\frac{3 \text{ mol O}_2}{2 \text{ mol Al}_2\text{O}_3}$ $\frac{2 \text{ mol Al}_2\text{O}_3}{3 \text{ mol O}_2}$

b. $3.7 \text{ mol Al}_2\text{O}_3 \times \frac{4 \text{ mol Al}}{2 \text{ mol Al}_2\text{O}_3} = 7.4 \text{ mol Al}$

12. a. $14.8 \text{ mol Al} \times \frac{3 \text{ mol O}_2}{4 \text{ mol Al}} = 11.1 \text{ mol O}_2$

b. $0.78 \text{ mol O}_2 \times \frac{2 \text{ mol Al}_2\text{O}_3}{3 \text{ mol O}_2} = 0.52 \text{ mol Al}_2\text{O}_3$

13. $5.00 \text{ g CaC}_2 \times \frac{1 \text{ mol CaC}_2}{64.1 \text{ g CaC}_2} \times \frac{1 \text{ mol C}_2\text{H}_2}{1 \text{ mol CaC}_2} \times \frac{26.0 \text{ g C}_2\text{H}_2}{1 \text{ mol C}_2\text{H}_2} = 2.03 \text{ g C}_2\text{H}_2$

14. $49.0 \text{ g H}_2\text{O} \times \frac{1 \text{ mol H}_2\text{O}}{18.0 \text{ g H}_2\text{O}} \times \frac{1 \text{ mol CaC}_2}{2 \text{ mol H}_2\text{O}} = 1.36 \text{ mol CaC}_2$

15. $6.54 \text{ g KClO}_3 \times \frac{1 \text{ mol KClO}_3}{122.6 \text{ g KClO}_3} \times \frac{3 \text{ mol O}_2}{2 \text{ mol KClO}_3} \times \frac{6.02 \times 10^{23} \text{ molecules O}_2}{1 \text{ mol O}_2} = 4.82 \times 10^{22} \text{ molecules O}_2$

16. $5.00 \times 10^{22} \text{ molecules NO} \times \frac{1 \text{ mol NO}}{6.02 \times 10^{23} \text{ molecules NO}} \times \frac{3 \text{ mol NO}_2}{1 \text{ mol NO}} \times \frac{46.0 \text{ g NO}_2}{1 \text{ mol NO}_2} = 11.5 \text{ g NO}_2$

Selected Solutions **R91**

17. $3.86\ \text{L CO} \times \frac{1\ \text{mol CO}}{22.4\ \text{L CO}} \times \frac{1\ \text{mol O}_2}{2\ \text{mol CO}} \times \frac{22.4\ \text{L O}_2}{1\ \text{mol O}_2} = 1.93\ \text{L O}_2$

18. $0.42\ \text{L H}_2 \times \frac{1\ \text{mol H}_2}{22.4\ \text{L H}_2} \times \frac{4\ \text{mol PH}_3}{6\ \text{mol H}_2} \times \frac{22.4\ \text{L PH}_3}{1\ \text{mol PH}_3} = 0.28\ \text{L PH}_3$

19. $27.9\ \text{mL O}_2 \times \frac{2\ \text{mL SO}_2}{3\ \text{mL O}_2} = 18.6\ \text{mL SO}_2$

20. $0.38\ \text{L SO}_2 \times \frac{1\ \text{L CO}_2}{2\ \text{L SO}_2} \times \frac{10\ \text{dL CO}_2}{1\ \text{L CO}_2} = 1.9\ \text{dL CO}_2$

26. $2.70\ \text{mol C}_2\text{H}_4 \times \frac{3\ \text{mol O}_2}{1\ \text{mol C}_2\text{H}_4} = 8.10\ \text{mol O}_2$

8.10 mol O_2 are needed to react with 2.70 mol C_2H_4, but there are only 6.30 mol O_2 given for the reaction. Therefore, O_2 is the limiting reagent.

27. $6.00\ \text{g HCl} \times \frac{1\ \text{mol HCl}}{36.5\ \text{g HCl}} = 0.160\ \text{mol HCl}$

$5.00\ \text{g Mg} \times \frac{1\ \text{mol Mg}}{24.3\ \text{g Mg}} = 0.210\ \text{mol Mg}$

$0.16\ \text{mol HCl} \times \frac{1\ \text{mol Mg}}{2\ \text{mol HCl}} = 0.080\ \text{mol Mg}$

HCl is the limiting reagent.

28. **a.** $2.70\ \text{mol C}_2\text{H}_4 \times \frac{2\ \text{mol O}_2}{1\ \text{mol C}_2\text{H}_4} = 5.40\ \text{mol O}_2$

C_2H_4 is the limiting reagent.

b. $2.70\ \text{mol C}_2\text{H}_4 \times \frac{2\ \text{mol H}_2\text{O}}{1\ \text{mol C}_2\text{H}_4} = 5.40\ \text{mol H}_2\text{O}$

29. $2.40\ \text{mol C}_2\text{H}_2 \times \frac{5\ \text{mol O}_2}{2\ \text{mol C}_2\text{H}_2} = 6.00\ \text{mol O}_2$

C_2H_2 is the limiting reagent.

$2.40\ \text{mol C}_2\text{H}_2 \times \frac{2\ \text{mol H}_2\text{O}}{2\ \text{mol C}_2\text{H}_2} \times \frac{18.0\ \text{g H}_2\text{O}}{1\ \text{mol H}_2\text{O}} = 43.2\ \text{g H}_2\text{O}$

30. $84.8\ \text{g Fe}_2\text{O}_3 \times \frac{1\ \text{mol Fe}_2\text{O}_3}{159.9\ \text{g Fe}_2\text{O}_3} \times \frac{2\ \text{mol Fe}}{1\ \text{mol Fe}_2\text{O}_3} \times \frac{55.9\ \text{g Fe}}{1\ \text{mol Fe}} = 59.3\ \text{g Fe}$

31. $\text{Cu}(s) + 2\text{AgNO}_3(aq) \longrightarrow 2\text{Ag}(s) + \text{Cu(NO}_3)_2(aq)$

$5.00\ \text{g Cu} \times \frac{1\ \text{mol Cu}}{63.6\ \text{g Cu}} \times \frac{2\ \text{mol Ag}}{1\ \text{mol Cu}} \times \frac{107.9\ \text{g Ag}}{1\ \text{mol Ag}} = 17.0\ \text{g Ag}$

32. $50.0\ \text{g SiO}_2 \times \frac{1\ \text{mol SiO}_2}{60.1\ \text{g SiO}_2} \times \frac{1\ \text{mol SiC}}{1\ \text{mol SiO}_2} \times \frac{40.1\ \text{g SiC}}{1\ \text{mol SiC}} = 33.36\ \text{g SiC}$

$\%\ \text{yield} = \frac{27.9\ \text{g SiC}}{33.4\ \text{g SiC}} \times 100\% = 83.5\%$

33. $\text{N}_2 + 3\text{H}_2 \longrightarrow 2\text{NH}_3$

$15.0\ \text{g N}_2 \times \frac{1\ \text{mol N}_2}{28.0\ \text{g N}_2} \times \frac{3\ \text{mol H}_2}{1\ \text{mol N}_2} \times \frac{2.0\ \text{g H}_2}{1\ \text{mol H}_2} = 3.2\ \text{g H}_2$

N_2 is the limiting reagent, so use the given mass of nitrogen to find the theoretical yield of NH_3.

$15.0\ \text{g N}_2 \times \frac{1\ \text{mol N}_2}{28.0\ \text{g N}_2} \times \frac{2\ \text{mol NH}_3}{1\ \text{mol N}_2} \times \frac{17.0\ \text{g NH}_3}{1\ \text{mol NH}_3} = 18.2\ \text{g NH}_3$

$\%\ \text{yield} = \frac{10.5\ \text{g NH}_3}{18.2\ \text{g NH}_3} \times 100\% = 57.7\%$

45. **a.** $2.7\ \text{mol C} \times \frac{1\ \text{mol CS}_2}{5\ \text{mol C}} = 0.54\ \text{mol CS}_2$

b. $5.44\ \text{mol SO}_2 \times \frac{5\ \text{mol C}}{2\ \text{mol SO}_2} = 13.6\ \text{mol C}$

c. $0.246\ \text{mol CS}_2 \times \frac{4\ \text{mol CO}}{1\ \text{mol CS}_2} = 0.984\ \text{mol CO}$

d. $118\ \text{mol CS}_2 \times \frac{2\ \text{mol SO}_2}{1\ \text{mol CS}_2} = 236\ \text{mol SO}_2$

46. **a.** $3.60 \times 10^2\ \text{g CH}_3\text{OH} \times \frac{1\ \text{mol CH}_3\text{OH}}{32.0\ \text{g CH}_3\text{OH}} \times \frac{1\ \text{mol CO}}{1\ \text{mol CH}_3\text{OH}} = 11.3\ \text{mol CO}$

$3.60 \times 10^2\ \text{g CH}_3\text{OH} \times \frac{1\ \text{mol CH}_3\text{OH}}{32.0\ \text{g CH}_3\text{OH}} \times \frac{2\ \text{mol H}_2}{1\ \text{mol CH}_3\text{OH}} = 22.5\ \text{mol H}_2$

b. $4.00\ \text{mol CH}_3\text{OH} \times \frac{1\ \text{mol CO}}{1\ \text{mol CH}_3\text{OH}} \times \frac{28.0\ \text{g CO}}{1\ \text{mol CO}} = 112\ \text{g CO}$

$4.00\ \text{mol CH}_3\text{OH} \times \frac{2\ \text{mol H}_2}{1\ \text{mol CH}_3\text{OH}} \times \frac{2.0\ \text{g H}_2}{1\ \text{mol H}_2} = 16\ \text{g H}_2$

c. $2.85\ \text{mol CO} \times \frac{2\ \text{mol H}_2}{1\ \text{mol CO}} \times \frac{2.0\ \text{g H}_2}{1\ \text{mol H}_2} = 11\ \text{g H}_2$

50. **a.** $32.9\ \text{g Li}_3\text{N} \times \frac{1\ \text{mol Li}_3\text{N}}{34.7\ \text{g Li}_3\text{N}} \times \frac{3\ \text{mol H}_2\text{O}}{1\ \text{mol Li}_3\text{N}} \times \frac{18.0\ \text{g H}_2\text{O}}{1\ \text{mol H}_2\text{O}} = 51.2\ \text{g H}_2\text{O}$

R92 Appendix E

b. $32.9\ \text{g } Li_3N \times \frac{1\ \text{mol } Li_3N}{34.7\ \text{g } Li_3N} \times \frac{1\ \text{mol } NH_3}{1\ \text{mol } Li_3N}$
$\times \frac{6.02 \times 10^{23}\ \text{molecules } NH_3}{1\ \text{mol } NH_3}$
$= 5.71 \times 10^{23}\ \text{molecules } NH_3$

c. $15.0\ \text{L } NH_3 \times \frac{1\ \text{mol } NH_3}{22.4\ \text{L } NH_3} \times \frac{1\ \text{mol } Li_3N}{1\ \text{mol } NH_3}$
$\times \frac{34.7\ \text{g } Li_3N}{1\ \text{mol } Li_3N} = 23.2\ \text{g } Li_3N$

53. **a.** $3.0\ \text{mol Al} \times \frac{3\ \text{mol } Cl_2}{2\ \text{mol Al}} = 4.5\ \text{mol } Cl_2$

Al is the limiting reagent.

b. $3.0\ \text{mol Al} \times \frac{2\ \text{mol } AlCl_3}{2\ \text{mol Al}} = 3.0\ \text{mol } AlCl_3$

c. $5.3\ \text{mol } Cl_2 - 4.5\ \text{mol } Cl_2 = 0.80\ \text{mol } Cl_2$

54. $15.0\ \text{g } Sb_2S_3 \times \frac{1\ \text{mol } Sb_2S_3}{339.9\ \text{g } Sb_2S_3} \times \frac{2\ \text{mol Sb}}{1\ \text{mol } Sb_2S_3}$
$\times \frac{121.8\ \text{g Sb}}{1\ \text{mol Sb}} = 10.8\ \text{g Sb}$

$\%\ \text{yield} = \frac{9.84\ \text{g Sb}}{10.8\ \text{g Sb}} \times 100\% = 91.1\%$

57. **a.** $1.49\ \text{g } HNO_3 \times \frac{1\ \text{mol } HNO_3}{63.0\ \text{g } HNO_3} \times \frac{4\ \text{mol Zn}}{10\ \text{mol } HNO_3}$
$\times \frac{6.02 \times 10^{23}\ \text{atoms Zn}}{1\ \text{mol Zn}} = 5.70 \times 10^{21}\ \text{atoms Zn}$

b. $29.1\ \text{g } NH_4NO_3 \times \frac{1\ \text{mol } NH_4NO_3}{80.0\ \text{g } NH_4NO_3}$
$\times \frac{4\ \text{mol Zn}}{1\ \text{mol } NH_4NO_3} \times \frac{65.4\ \text{g Zn}}{1\ \text{mol Zn}} = 95.2\ \text{g Zn}$

60. **a.** $1.0\ \text{kg } N_2H_4 \times \frac{10^3\ \text{g } N_2H_4}{1.0\ \text{kg } N_2H_4} \times \frac{1\ \text{mol } N_2H_4}{32.0\ \text{g } N_2H_4}$
$\times \frac{1\ \text{mol } N_2}{1\ \text{mol } N_2H_4} \times \frac{22.4\ \text{L } N_2}{1\ \text{mol } N_2} = 7.0 \times 10^2\ \text{L } N_2$

$1.2\ \text{kg } O_2 \times \frac{10^3\ \text{g } O_2}{1\ \text{kg } O_2} \times \frac{1\ \text{mol } O_2}{32.0\ \text{g } O_2} \times \frac{1\ \text{mol } N_2}{1\ \text{mol } O_2}$
$\times \frac{22.4\ \text{L } N_2}{1\ \text{mol } N_2} = 8.4 \times 10^2\ \text{L } N_2$

Since $7.0 \times 10^2\ \text{L } N_2 < 8.4 \times 10^2\ \text{L } N_2$, the limiting reagent is N_2H_4 and O_2 is in excess.

b. $1.0\ \text{kg } N_2H_4 \times \frac{10^3\ \text{g } N_2H_4}{1\ \text{kg } N_2H_4} \times \frac{1\ \text{mol } N_2H_4}{32.0\ \text{g } N_2H_4} \times$
$\frac{1\ \text{mol } O_2}{1\ \text{mol } N_2H_4} \times \frac{32.0\ \text{g } O_2}{1\ \text{mol } O_2} = 1.0 \times 10^3\ \text{g } O_2 \text{ used}$

$1.0 \times 10^3\ \text{g } O_2 \times \frac{1\ \text{kg } O_2}{10^3\ \text{g } O_2} = 1.0\ \text{kg } O_2$

$1.2\ \text{kg } O_2 - 1.0\ \text{kg } O_2 = 0.2\ \text{kg } O_2$

The excess remaining reagent is $0.2\ \text{kg } O_2$.

64. $158\ \text{g } CH_4 \times \frac{1\ \text{mol } CH_4}{16.0\ \text{g } CH_4} \times \frac{3\ \text{mol } H_2}{1\ \text{mol } CH_4}$
$\times \frac{6.02 \times 10^{23}\ \text{molecules } H_2}{1\ \text{mol } H_2} = 1.78 \times 10^{25}\ \text{molecules } H_2$

67. **a.** $SF_2(l) + 2F_2(g) \longrightarrow SF_6(g)$

b. $5.00\ \text{mg } SF_2 \times \frac{1\ \text{g } SF_2}{10^3\ \text{mg } SF_2} \times \frac{1\ \text{mol } SF_2}{70.1\ \text{g } SF_2}$
$\times \frac{2\ \text{mol } F_2}{1\ \text{mol } SF_2} \times \frac{6.02 \times 10^{23}\ \text{molecules } F_2}{1\ \text{mol } F_2}$
$= 8.59 \times 10^{19}\ \text{molecules}$

c. $6.66\ \text{g } SF_2 \times \frac{1\ \text{mol } SF_2}{70.1\ \text{g } SF_2} \times \frac{2\ \text{mol } F_2}{1\ \text{mol } SF_2} \times \frac{22.4\ \text{L } F_2}{1\ \text{mol } F_2}$
$= 4.26\ \text{L } F_2$

69. B ⟶ C:

$\%\ \text{yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\%$
$= \frac{2.00\ \text{mol C}}{4.00\ \text{mol C}} \times 100\% = 50.0\%$

C ⟶ D:

Let x represent the actual yield of compound D.

$\%\ \text{yield} = 25.0\% = \frac{x}{2\ \text{mol D}} \times 100\%$

$x = 0.250 \times 2\ \text{mol D}$
$x = 0.500\ \text{mol D}$

D ⟶ E:

Let y represent the actual yield of compound E.

$\%\ \text{yield} = 10.0\% = \frac{y}{0.500\ \text{mol E}} \times 100\%$

$y = 0.100 \times 0.500\ \text{mol E}$
$y = 0.0500\ \text{mol E}$

E ⟶ F:

$\%\ \text{yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\%$
$= \frac{0.0100\ \text{mol F}}{0.0500\ \text{mol F}} \times 100\% = 20.0\%$

Selected Solutions **R93**

72. **a.** $2Ca_3(PO_4)_2 + 6SiO_2 \longrightarrow P_4O_{10} + 6CaSiO_3$

$P_4O_{10} + 10C \longrightarrow P_4 + 10CO$

b. $5.5 \times 10^5 \text{ g } Ca_3(PO_4)_2 \times \frac{1 \text{ mol } Ca_3(PO_4)_2}{310.3 \text{ g } Ca_3(PO_4)_2} \times \frac{1 \text{ mol } P_4O_{10}}{2 \text{ mol } Ca_3(PO_4)_2} = 8.9 \times 10^2 \text{ mol } P_4O_{10}$

$2.3 \times 10^5 \text{ g } SiO_2 \times \frac{1 \text{ mol } SiO_2}{60.1 \text{ g } SiO_2} \times \frac{1 \text{ mol } P_4O_{10}}{6 \text{ mol } SiO_2} = 6.4 \times 10^2 \text{ mol } P_4O_{10}$

Since $6.4 \times 10^2 \text{ mol } P_4O_{10} < 8.9 \times 10^2 \text{ mol } P_4O_{10}$, SiO_2 is the limiting reagent.

c. $6.4 \times 10^2 \text{ mol } P_4O_{10} \times \frac{1 \text{ mol } P_4}{1 \text{ mol } P_4O_{10}} \times \frac{124.0 \text{ g } P_4}{1 \text{ mol } P_4} = 7.9 \times 10^4 \text{ g } P_4$

d. $6.4 \times 10^2 \text{ mol } P_4O_{10} \times \frac{10 \text{ mol C}}{1 \text{ mol } P_4O_{10}} \times \frac{12.0 \text{ g C}}{1 \text{ mol C}} = 7.7 \times 10^4 \text{ g C}$

75. The balanced equation is:

$C_6H_{12}O_6 \longrightarrow 2C_2H_5OH + 2CO_2$

$1.0 \times 10^3 \text{ kg } C_6H_{12}O_6 \times \frac{10^3 \text{ g } C_6H_{12}O_6}{1 \text{ kg } C_6H_{12}O_6} \times \frac{1 \text{ mol } C_6H_{12}O_6}{180.0 \text{ g } C_6H_{12}O_6} \times \frac{2 \text{ mol } C_2H_5OH}{1 \text{ mol } C_6H_{12}O_6} \times \frac{46.0 \text{ g } C_2H_5OH}{1 \text{ mol } C_2H_5OH} \times \frac{1 \text{ kg } C_2H_5OH}{10^3 \text{ g } C_2H_5OH} \times \frac{5.0 \text{ K}}{8 \text{ kg } C_2H_5OH} \times \frac{1 \text{ day}}{24 \text{ K}} = 13 \text{ days}$

78. First calculate the amount of $CaCO_3$ needed to produce 81.8 g of $CaCl_2$:

$81.8 \text{ g } CaCl_2 \times \frac{1 \text{ mol } CaCl_2}{111.0 \text{ g } CaCl_2} \times \frac{1 \text{ mol } CaCO_3}{1 \text{ mol } CaCl_2} \times \frac{100.1 \text{ g } CaCO_3}{1 \text{ mol } CaCO_3} = 73.8 \text{ g } CaCO_3$

Then calculate % $CaCO_3$ in the limestone:

$\frac{73.8 \text{ g } CaCO_3}{84.4 \text{ g limestone}} \times 100\% = 87.4\% \text{ } CaCO_3$

82. **a.** $4NH_3 + 5O_2 \longrightarrow 4NO + 6H_2O$

$2NO + O_2 \longrightarrow 2NO_2$

$3NO_2 + H_2O \longrightarrow 2HNO_3 + NO$

b. $88.0 \text{ g } NH_3 \times \frac{14.0 \text{ g N}}{17.0 \text{ g } NH_3} \times \frac{63.0 \text{ g } HNO_3}{14.0 \text{ g N}} = 326 \text{ g } HNO_3$

c. 70.0% of 1 kg HNO_3 = 700 g HNO_3

$700 \text{ g } HNO_3 \times \frac{88.0 \text{ g } NH_3}{326 \text{ g } HNO_3} = 189 \text{ g } NH_3$

88. **a.** 22, 22, 25 **c.** 8, 8, 10

b. 50, 50, 70 **d.** 12, 12, 14

99. $(3 \times 9.0) + (2 \times 27.0) + (6 \times 28.1) + (18 \times 16.0) = 537.6$

$147 \text{ g } Be_3Al_2Si_6O_{18} \times \frac{27.0 \text{ g Be}}{537.6 \text{ g } Be_3Al_2Si_6O_{18}} = 7.38 \text{ g Be}$

101. $90 \text{ g} \times 0.267 = 24 \text{ g C}$

$24 \text{ g C} \times \frac{1 \text{ mol C}}{12.0 \text{ g C}} = 2.0 \text{ mol C}$

$90 \text{ g} \times 0.022 = 2.0 \text{ g H}$

$2.0 \text{ g H} \times \frac{1 \text{ mol H}}{1.0 \text{ g H}} = 2.0 \text{ mol H}$

$90 \text{ g} \times 0.711 = 64 \text{ g O}$

$64 \text{ g O} \times \frac{1 \text{ mol O}}{16.0 \text{ g O}} = 4.0 \text{ mol O}$

The empirical formula is $C_2H_2O_4$.

Chapter 13

1. $385 \text{ mm Hg} \times \frac{101.3 \text{ kPa}}{760 \text{ mm Hg}} = 51.3 \text{ kPa}$

$51.3 \text{ kPa} \times \frac{1 \text{ atm}}{101.3 \text{ kPa}} = 0.507 \text{ atm}$

2. $33.7 \text{ kPa} \times \frac{1 \text{ atm}}{101.3 \text{ kPa}} = 0.33 \text{ atm} > 0.25 \text{ atm}$

31. In an elastic collision, energy is transferred between particles.

35. **a.** $190 \text{ mm Hg} \times \frac{101.3 \text{ kPa}}{760 \text{ mm Hg}} = 25 \text{ kPa}$

b. $190 \text{ mm Hg} \times \frac{1 \text{ atm}}{760 \text{ mm Hg}} = 0.25 \text{ atm}$

40. Since the Kelvin temperature is directly proportional to the average kinetic energy and the temperature increased from 300 K to 900 K, then the average kinetic energy triples as well.

43. Two opposing processes are occurring at identical rates.

49. Escaping molecules have more kinetic energy than the average. Thus, the average kinetic energy and temperature of the remaining molecules are lower.

52. The intermolecular attractions between molecules are weaker than the attractions between ions.

53. Water from the food sublimed and then condensed on the lid.

55. The average kinetic energy of the molecules is greater because, by definition, a fever is a state of increased body temperature.

R94 Appendix E

60. Decrease; as the attractions become stronger, it becomes more difficult for molecules to overcome the attractions and vaporize.

63. The Kelvin temperature is directly proportional to the average kinetic energy. As the temperature rises, the air particles speed up and increase in kinetic energy which causes the raft to expand. As the temperature drops, the air particles slow down resulting in a decrease in kinetic energy, which causes the raft to not be fully inflated.

65. Possible answer: Since the beaker is an open container, the water should boil at 100°C at or close to sea level. Your partner probably misread the thermometer and should recheck the value.

72. No; at 15 kPa, water would boil at a temperature of about 50°C, which is much higher than room temperature.

76. No; if (a) > (b) then water vapor will condense at a greater rate than the liquid evaporates.

79. **a.** body-centered cubic

$$900 \times \text{molar mass}_g = 5625 \times 32.0\ g$$

$$\text{molar mass}_g = \frac{180{,}000\ g}{900} = 200\ g$$

R96 Appendix E

94. **a.** $T = 120°C + 273 = 393\ K$

$$34.0\ \cancel{g\ NH_3} \times \frac{1\ mol\ NH_3}{17.0\ \cancel{g\ NH_3}} = 2\ mol\ NH_3$$

$$96.0\ \cancel{g\ O_2} \times \frac{1\ mol\ O_2}{32.0\ \cancel{g\ O_2}} = 3\ mol\ O_2$$

$$2\ \cancel{mol\ NH_3} \times \frac{5\ mol\ O_2}{4\ \cancel{mol\ NH_3}} = 2.5\ mol\ O_2$$

$2.5\ mol\ O_2 < 3\ mol\ O_2$, so NH_3 is limiting reagent.

$$n_{NO} = 2\ \cancel{mol\ NH_3} \times \frac{4\ mol\ NO}{4\ \cancel{mol\ NH_3}} = 2\ mol\ NO$$

$$P = \frac{n \times R \times T}{V}$$

$$P_{NO} = \frac{2\ \cancel{mol} \times 8.31 \frac{\cancel{L} \cdot kPa}{\cancel{K} \cdot \cancel{mol}} \times 393\ \cancel{K}}{40.0\ \cancel{L}} = 163\ kPa$$

b. $$n_{H_2O} = 2\ \cancel{mol\ NH_3} \times \frac{6\ mol\ H_2O}{4\ \cancel{mol\ NH_3}} = 3\ mol\ H_2O$$

$$P_{H_2O} = \frac{3\ \cancel{mol} \times 8.31 \frac{\cancel{L} \cdot kPa}{\cancel{K} \cdot \cancel{mol}} \times 393\ \cancel{K}}{40.0\ \cancel{L}} = 245\ kPa$$

O_2 is in excess by 0.5 mol.

$$P_{O_2} = \frac{0.5\ \cancel{mol} \times 8.31 \frac{\cancel{L} \cdot kPa}{\cancel{K} \cdot \cancel{mol}} \times 393\ \cancel{K}}{40.0\ \cancel{L}} = 41\ kPa$$

$$P_{total} = P_{O_2} + P_{NO} + P_{H_2O}$$
$$= 41\ kPa + 163\ kPa + 245\ kPa = 449\ kPa$$

96. **b.** 700 mm Hg

c. directly proportional

d. The pressure rises 2.4 mm of Hg for every 1°C.

$$\text{slope of line } (m) = \frac{750\ mm\ Hg - 726\ mm\ Hg}{20°C - 10°C}$$
$$= \frac{24\ mm\ Hg}{10°C} = 2.4\ mm\ Hg/°C$$

e. $m = 2.4$; y-intercept = 700 mm Hg;
equation of line:
$P = (2.4\ mm\ Hg/°C)T + 700\ mm\ Hg$

f. Gay-Lussac's law; sample data points:
$(T_1, P_1) = (10°C, 726\ mm\ Hg)$
$(T_2, P_2) = (20°C, 750\ mm\ Hg)$

$T_1 = 10°C + 273 = 283\ K$
$T_1 = 20°C + 273 = 293\ K$

$$\frac{P_1}{T_1} = \frac{P_2}{T_2}$$

$$\frac{726\ mm\ Hg}{283\ K} = \frac{750\ mm\ Hg}{293\ K} = 2.6\ mm\ Hg/K$$

99. Let $n_{initial}$ represent moles of methane/ethyne.

$n_{initial} = n_{CH_4} + n_{C_2H_2}$ [equation 1]

Let n_{CO_2} represent final moles of CO_2. $PV = nRT$, so $V = nRT/P$. At constant volume and temperature:

$$V = \frac{n_{CO_2} \times \cancel{R} \times \cancel{T}}{25.2\ kPa} = \frac{n_{initial} \times \cancel{R} \times \cancel{T}}{16.8\ kPa}$$

$$n_{CO_2} \times 16.8\ kPa = 25.2\ kPa \times n_{initial}$$

$$n_{CO_2} = \frac{25.2\ \cancel{kPa}}{16.8\ \cancel{kPa}} \times n_{initial}$$

$n_{CO_2} = 1.5 n_{initial}$ [equation 2]

Chemical equations for combustion:

$CH_4 + 2O_2 \longrightarrow CO_2 + 2H_2O$
(Each mol CH_4 burned yields 1 mol CO_2.)

$C_2H_2 + \frac{5}{2}O_2 \longrightarrow 2CO_2 + H_2O$
(Each mol C_2H_2 burned yields 2 mol CO_2.)

Therefore, $n_{CO_2} = n_{CH_4} + 2n_{C_2H_2}$ [equation 3]

Substitute equation 2 into equation 3:
$1.5 n_{initial} = n_{CH_4} + 2n_{C_2H_2}$

Substitute for $n_{initial}$ using equation 1:

$1.5(n_{CH_4} + n_{C_2H_2}) = n_{CH_4} + 2n_{C_2H_2}$

$n_{CH_4} = n_{C_2H_2}$

So, in terms of moles, the initial mixture is equal parts methane and ethyne, or 50% methane (CH_4).

100. Let x be the percentage of total gas volume occupied by its molecules.

$$V_{H_2\ molecules} = 3.0 \times 10^{20}\ \cancel{molecules\ H_2} \times \frac{6.7 \times 10^{-24}\ m\cancel{L}}{1\ \cancel{molecule\ H_2}} \times \frac{1\ L}{10^3\ \cancel{mL}} = 2.0 \times 10^{-6}\ L$$

a. $$\frac{V_{molecules}}{V_{gas}} \times 100\% = \frac{2.0 \times 10^{-6}\ \cancel{L}}{0.10\ \cancel{L}} \times 100\% = 2.0 \times 10^{-3}\%$$

b. $$\frac{V_{molecules}}{V_{gas}} \times 100\% = \frac{2.0 \times 10^{-6}\ \cancel{L}}{1 \times 10^{-4}\ \cancel{L}} \times 100\% = 2.0\%$$

107. $h = 1.60\ mm = 0.160\ cm$

$V = l \times w \times h = 4.50\ cm \times 1.30\ cm \times 0.160\ cm = 0.936\ cm^3$

$$\text{Density} = \frac{\text{mass}}{\text{volume}} = \frac{9.92\ g}{0.936\ cm^3} = 10.6\ g/cm^3$$

113. **a.** tin(II) bromide

b. barium sulfate

c. magnesium hydroxide

d. iodine pentafluoride

Selected Solutions **R97**

115. **a.** molar mass of $Ca(CH_3CO_2)_2$ = (1 × 40.1 g/mol) + (4 × 12.0 g/mol) + (6 × 1.0 g/mol) + (4 × 16.0 g/mol) = 158.1 g/mol

b. molar mass of H_3PO_4= (3 × 1.0 g/mol) + (1 × 31.0 g/mol) + (4 × 16.0 g/mol) = 98.0 g/mol

c. molar mass of $C_{12}H_{22}O_{11}$ = (12 × 12.0 g/mol) + (22 × 1.0 g/mol) + (11 × 16.0 g/mol) = 342.0 g/mol

d. molar mass of $Pb(NO_3)_2$ = (1 × 207.2 g/mol) + (2 × 14.0 g/mol) + (6 × 16.0 g/mol) = 331.2 g/mol

117. **a.** efm of C_2H_4O = (2 × 12.0g/mol) + (4 × 1.0 g/mol) + (1 × 16.0 g/mol) = 44.0 g/mol

$$\frac{\text{molar mass}}{\text{efm}} = \frac{88\ \cancel{\text{g/mol}}}{44.0\ \cancel{\text{g/mol}}} = 2$$

$(C_2H_4O) \times 2 = C_4H_8O_2$

b. efm of CH = 12.0 g/mol + 1.0 g/mol = 13.0 g/mol

$$\frac{\text{molar mass}}{\text{efm}} = \frac{104\ \cancel{\text{g/mol}}}{13.0\ \cancel{\text{g/mol}}} = 8$$

$(CH) \times 8 = C_8H_8$

c. $\%C = 26.7\% = \dfrac{\text{mass of C}}{90\text{ g}} \times 100\%$

mass of C = 0.267 × 90 g = 24 g

$$24\ \cancel{\text{g C}} \times \frac{1\text{ mol C}}{12.0\ \cancel{\text{g C}}} = 2.0\text{ mol C}$$

$\%O = 71.1\% = \dfrac{\text{mass of O}}{90\text{ g}} \times 100\%$

mass of O = 0.711 × 90 g = 64 g

$$64\ \cancel{\text{g O}} \times \frac{1\text{ mol O}}{16.0\ \cancel{\text{g O}}} = 4.0\text{ mol O}$$

$\%H = 2.2\% = \dfrac{\text{mass of H}}{90\text{ g}} \times 100\%$

mass of H = 0.022 × 90 g = 2.0 g

$$2.0\ \cancel{\text{g H}} \times \frac{1\text{ mol H}}{1.0\ \cancel{\text{g H}}} = 2.0\text{ mol H}$$

The empirical formula is $C_2H_2O_4$. Since molar mass/efm = 1, $C_2H_2O_4$ is both the empirical formula and molecular formula

121. **a.** $4Al(s) + 3O_2(g) \longrightarrow 2Al_2O_3(s)$

b. $583\ \cancel{\text{g } Al_2O_3} \times \dfrac{1\text{ mol } Al_2O_3}{102\ \cancel{\text{g } Al_2O_3}} = 5.72\text{ mol } Al_2O_3$

$$5.72\ \cancel{\text{g } Al_2O_3} \times \frac{4\ \cancel{\text{mol Al}}}{2\ \cancel{\text{mol } Al_2O_3}} \times \frac{27.0\text{ g Al}}{1\ \cancel{\text{mol Al}}} = 309\text{ g Al}$$

$$5.72\ \cancel{\text{g } Al_2O_3} \times \frac{3\ \cancel{\text{mol } O_2}}{2\ \cancel{\text{mol } Al_2O_3}} \times \frac{32.0\text{ g } O_2}{1\ \cancel{\text{mol } O_2}} = 275\text{ g } O_2$$

Chapter 15

8. mass of 5 mol H_2O = 5[(2 × 1.0 g) + 16.0 g] = 90.0 g

molar mass of $CuSO_4 \cdot H_2O$ = 63.5 g + 32.1 g + (4 × 16.0 g) + 90.0 g = 249.6 g

$$\%\text{ by mass } H_2O = \frac{\text{mass of water}}{\text{mass of hydrate}} \times 100\% = \frac{90.0\ \cancel{\text{g}}}{249.6\ \cancel{\text{g}}} \times 100\% = 36.1\%$$

9. $5.00\ \cancel{\text{g } Na_2CO_3} \times \dfrac{100.0\text{ g } Na_2CO_3 \cdot 10\ H_2O}{37.06\ \cancel{\text{g } Na_2CO_3}} =$

$13.5\text{ g } Na_2CO_3 \cdot 10H_2O$

25. Surface molecules are attracted to the liquid molecules below but not to the air. Molecules inside the liquid are attracted in all directions.

28. A surfactant is a wetting agent such as soap or detergent. A surfactant interferes with hydrogen bonding between water molecules and reduces surface tension.

31. Water has low vapor pressure.

35. Bodies of water would freeze from the bottom up. This would kill many forms of aquatic life.

38. Solvent: water; solute: sugar

39. No; the molecules and ions are smaller than the pores of the filter and would therefore pass through the filter.

40. Solvent molecules surround positively charged and negatively charged ions.

43. **a.** HCl (polar) dissolves.

b. K_2SO_4 (ionic) dissolves.

c. NaI (ionic) dissolves.

d. C_2H_6 (nonpolar) will not dissolve.

e. NH_3 (polar) dissolves.

f. $CaCO_3$ (strong ionic forces) will not dissolve.

45. Its ions are free to move toward positively and negatively charged electrodes.

R98 Appendix E

48. a. $Na_2SO_4 \cdot 10H_2O$

b. $CaCl_2 \cdot 2H_2O$

c. $Ba(OH)_2 \cdot 8H_2O$

49. a. tin(IV) chloride pentahydrate

b. iron(II) sulfate heptahydrate

c. barium bromide tetrahydrate

d. iron(III) phosphate tetrahydrate

50. $MgSO_4 \cdot 7H_2O(s) \longrightarrow MgSO_4 \cdot H_2O(s) + 6H_2O(g)$

52. Hygroscopic substances absorb water vapor from the air and create a dry environment in a sealed container.

54. solutions, colloids, suspensions

55. Colloids and suspensions exhibit the Tyndall effect, but solutions do not. The particles in a suspension will settle out over time.

59. Brownian motion and repulsion between like-charged ions adsorbed on the surfaces of colloidal particles.

62. hexane, ethanol, water

63. a. 1.0000 g/mL b. 4°C

c. No; there would be a break in the curve at 0°C as liquid water at 0°C changes to ice at 0°C.

65. Hydrobromic acid disassociates into hydrogen and bromide ions when dissolved in water, but methanol does not.

66. a. Water expands when it freezes to ice.

b. Water is polar, and wax is nonpolar; water has a higher surface tension.

c. Water has a lower vapor pressure than alcohol.

68. a. gasoline c. water

b. gasoline d. water

69. a. No, both form clear, colorless solutions.

b. Evaporate the water to examine the crystals; test for electrical conductivity; do a flame test.

72. a. $NH_4Cl(s) \longrightarrow NH_4^+(aq) + Cl^-(aq)$

b. $C_2H_4O_2(s) \longrightarrow H^+(aq) + C_2H_3O_2^-(aq)$

c. $Cu(NO_3)_2(s) \longrightarrow Cu^{2+}(aq) + 2NO_3^-(aq)$

d. $HgCl_2(s) \longrightarrow Hg^{2+}(aq) + 2Cl^-(aq)$

73. a. sodium carbonate monohydrate;

mass of 1 mol $H_2O = (2 \times 1.0\ g) + 16.0\ g = 18.0\ g$

molar mass of $Na_2CO_3 \cdot H_2O = (2 \times 23.0\ g) + 12.0\ g + (3 \times 16.0\ g) + 18.0\ g = 124.0\ g$

$$\%\ \text{by mass } H_2O = \frac{18.0\ \cancel{g}}{124.0\ \cancel{g}} \times 100\% = 14.5\%$$

b. magnesium sulfate heptahydrate;

mass of 7 mol $H_2O = 7[(2 \times 1.0\ g) + 16.0\ g] = 126.0\ g$

molar mass of $MgSO_4 \cdot 7H_2O = 24.3\ g + 32.1\ g + (4 \times 16.0\ g) + 126.0\ g = 246.4\ g$

$$\%\ \text{by mass } H_2O = \frac{126.0\ \cancel{g}}{246.4\ \cancel{g}} \times 100\% = 51.14\%$$

75. a. $Ba(OH)_2(s) + 8H_2O(l) \longrightarrow Ba(OH)_2 \cdot 8H_2O(s)$

b. mass of 8 mol $H_2O = 8[(2 \times 1.0\ g) + 16.0\ g] = 144.0\ g$

molar mass of $Ba(OH)_2 \cdot 8H_2O = 137.3\ g + 2(16.0\ g + 1.0\ g) + 144.0\ g = 315.3\ g$

$$\%\ \text{by mass } H_2O = \frac{144.0\ \cancel{g}}{315.3\ \cancel{g}} \times 100\% = 45.67\%$$

76. From Practice Problem 8, the percent H_2O in $CuSO_4 \cdot 5H_2O$ is 36.1%. This means that for every 100.0 g of hydrate, there are 100.0 g − 36.1 g = 63.9 g of anhydrous $CuSO_4$.

$$10.0\ \cancel{g\ CuSO_4} \times \frac{100.0\ g\ CuSO_4 \cdot 5H_2O}{63.9\ \cancel{g\ CuSO_4}} = 15.6\ g\ CuSO_4 \cdot 5H_2O$$

78. a. (1), (3), (6), (8)

b. (1), (2), (5), (6), (7), (9)

c. (2), (4), (5)

80. a. nonelectrolyte

b. weak electrolyte

c. strong electrolyte

81. The container would break because water expands as it freezes.

83. The surface tension of water keeps the strider from sinking. The surfactant would reduce the surface tension and the strider would shrink.

85. The hydrogen-bonded structures in liquid water are disrupted when ethyl alcohol is added because the alcohol competes for hydrogen bonds with water molecules and the water structure collapses. Thus, mixtures of water and ethyl alcohol have less volume than the sum of the volumes of the components. Mixing two liquids could result in a volume greater than the sum of the volumes of the components if the structural ordering in the mixture is greater than in the separated components.

86. Most of the important chemical reactions of life take place in aqueous solutions inside cells.

Selected Solutions **R99**

89. **a.** pink **b.** pink **c.** blue

d. mass of 6 mol H_2O = 6[(2 × 1.0 g) + 16.0 g] = 108.0 g

molar mass of $CoCl_2 \cdot 6H_2O$ = 58.9 g + (2 × 35.5 g) + 108.0 g = 237.9 g

$$\%\text{ by mass } H_2O = \frac{108.0\ \cancel{g}}{237.9\ \cancel{g}} \times 100\% = 45.40\%$$

e. water or water vapor

91. In spring, when the ice melts and the temperature of the surface water increases to 4°C, it becomes heavier than the water below it and sinks. The downward movement of surface water forces water in the deeper parts of the lake upward, where it is warmed.

92. A surfactant helps to wet the burning material, so less water is needed to put out the fire. Thus, less water carries pollutants into the environment.

93. Water enters cracks in pavement and expands when it freezes, creating larger cracks. Continuous freeze-thaw cycles cause pavement to break up and form potholes.

97. The molecules in the dirt and grease dissolve in the water.

100. **a.** 5 **b.** 2 **c.** 2 **d.** 4

102.

104. **a.** $6CO_2(g) + 6H_2O(l) \longrightarrow C_6H_{12}O_6(s) + 6O_2(g)$

$6.52 \text{ mol } C_2H_6O$

$n_{H_2O} = 500 \text{ g } H_2O \times \dfrac{1 \text{ mol } H_2O}{18.0 \text{ g } H_2O} = 27.8 \text{ mol } H_2O$

$X_{C_2H_6O} = \dfrac{n_{C_2H_6O}}{n_{C_2H_6O} + n_{H_2O}} = \dfrac{6.52 \text{ mol}}{27.8 \text{ mol} + 6.52 \text{ mol}} = 0.190$

$X_{H_2O} = \dfrac{n_{H_2O}}{n_{C_2H_6O} + n_{H_2O}} = \dfrac{27.8 \text{ mol}}{27.8 \text{ mol} + 6.52 \text{ mol}} = 0.810$

37. $n_{CCl_4} = 50.0 \text{ g } CCl_4 \times \dfrac{1 \text{ mol } CCl_4}{153.8 \text{ g } CCl_4} = 0.325 \text{ mol } CCl_4$

$n_{CHCl_3} = 50.0 \text{ g } CHCl_3 \times \dfrac{1 \text{ mol } CHCl_3}{119.4 \text{ g } CHCl_3}$

$= 0.419 \text{ mol } CHCl_3$

$X_{CCl_4} = \dfrac{n_{CCl_4}}{n_{CCl_4} + n_{CHCl_3}} = \dfrac{0.325 \text{ mol}}{0.325 \text{ mol} + 0.419 \text{ mol}}$

$= 0.437$

$X_{CHCl_3} = \dfrac{n_{CHCl_3}}{n_{CCl_4} + n_{CHCl_3}} = \dfrac{0.419 \text{ mol}}{0.325 \text{ mol} + 0.419 \text{ mol}}$

$= 0.563$

38. $10.0 \text{ g } C_6H_{12}O_6 \times \dfrac{1 \text{ mol } C_6H_{12}O_6}{180.0 \text{ g } C_6H_{12}O_6} =$

$0.0556 \text{ mol } C_6H_{12}O_6$

$m = \dfrac{0.0556 \text{ mol } C_6H_{12}O_6}{50.0 \text{ g } H_2O \times \dfrac{1 \text{ kg } H_2O}{10^3 \text{ g } H_2O}} = 1.11m \text{ } C_6H_{12}O_6$

$\Delta T_f = K_f \times m = 1.86°\text{C}/m \times 1.11m = 2.06°\text{C}$

39. $200 \text{ g } C_3H_6O \times \dfrac{1 \text{ mol } C_3H_6O}{58.0 \text{ g } C_3H_6O} = 3.45 \text{ mol } C_3H_6O$

$m = \dfrac{3.45 \text{ mol } C_3H_6O}{400 \text{ g benzene} \times \dfrac{1 \text{ kg benzene}}{10^3 \text{ g benzene}}} = 8.63m \text{ } C_3H_6O$

$\Delta T_f = K_f \times m = 5.12°\text{C}/m \times 8.62m = 44.2°\text{C}$

40. $m = \dfrac{1.25 \text{ mol } CaCl_2}{1400 \text{ g } H_2O \times \dfrac{1 \text{ kg } H_2O}{10^3 \text{ g } H_2O}} = 0.893m \text{ } CaCl_2$

Each formula unit of $CaCl_2$ disassociates into 3 particles, so molality of total particles is:

$3 \times 0.893m = 2.68m$

$\Delta T_b = K_b \times m = 0.512°\text{C}/m \times 2.68m = 1.37°\text{C}$

$T_b = 100°\text{C} + 1.37°\text{C} = 101.37°\text{C}$

41. $m = \dfrac{\Delta T_b}{K_b} = \dfrac{2.00°\text{C}}{0.512°\text{C}/m} = 3.91m$

(molality of total particles)

Each formula unit of NaCl disassociates into 2 particles, so the solution concentration is:

$3.91m/2 = 1.96m$

Mass of NaCl needed per 1 kg of H_2O is:

$1.96 \text{ mol NaCl} \times \dfrac{58.5 \text{ g NaCl}}{1 \text{ mol NaCl}} = 115 \text{ g NaCl}$

55. a. $S_2 = \dfrac{S_1 \times P_2}{P_1} = \dfrac{0.026 \text{ g/L} \times 0.60 \text{ atm}}{1.00 \text{ atm}} = 0.016 \text{ g/L}$

b. $S_2 = \dfrac{S_1 \times P_2}{P_1} = \dfrac{0.026 \text{ g/L} \times 1.80 \text{ atm}}{1.00 \text{ atm}} = 0.047 \text{ g/L}$

58. $V_1 = \dfrac{M_2 \times V_2}{M_1} = \dfrac{0.100M \times 100.0 \text{ mL}}{0.500M} = 20.0 \text{ mL}$

59. $\dfrac{0.50 \text{ g NaCl}}{100 \text{ mL}} \times \dfrac{1 \text{ mol NaCl}}{58.5 \text{ g NaCl}} \times \dfrac{10^3 \text{ mL}}{1 \text{ L}} = 0.085M$

61. a. $2500 \text{ g solution} \times \dfrac{0.90 \text{ g NaCl}}{100 \text{ g solution}} = 23 \text{ g NaCl}$

b. $0.050 \text{ kg solution} \times \dfrac{1000 \text{ g solution}}{1 \text{ kg solution}} \times \dfrac{4.0 \text{ g } MgCl_2}{100 \text{ g solution}}$

$= 2.0 \text{ g } MgCl_2$

63. a. $\dfrac{25 \text{ mL ethanol}}{150 \text{ mL}} \times 100\% = 17\% \text{ (v/v) ethanol}$

b. $\dfrac{175 \text{ mL isopropyl alcohol}}{275 \text{ mL}} \times 100\% =$

63.6% (v/v) isopropyl alcohol

Selected Solutions **R101**

72. **a.** Molality of $Na_2SO_4 = \dfrac{1.40 \text{ mol } Na_2SO_4}{1750 \text{ g } H_2O \times \dfrac{1 \text{ kg } H_2O}{10^3 \text{ g } H_2O}}$

$= 0.800m \text{ } Na_2SO_4$

Each mol of Na_2SO_4 that dissolves yields 3 mol of particles.

Molality of total particles $= 3 \times 0.800m = 2.40m$

$\Delta T_f = K_f \times m = 1.86°C/m \times 2.40 m = 4.46°C$

$T_f = 0°C - 4.46°C = -4.46°C$

b. Molality of $MgSO_4 = \dfrac{0.060 \text{ mol } MgSO_4}{100 \text{ g } H_2O \times \dfrac{1 \text{ kg } H_2O}{10^3 \text{ g } H_2O}}$

$= 0.60m \text{ } MgSO_4$

Each mol of $MgSO_4$ that dissolves yields 2 mol of particles.

Molality of total particles $= 2 \times 0.60m = 1.2m$

$\Delta T_f = K_f \times m = 1.86°C/m \times 1.2m = 2.2°C$

$T_f = 0°C - 22°C = -2.2°C$

76. $12.0 \text{ g } C_{10}H_8 \times \dfrac{1 \text{ mol } C_{10}H_8}{128.0 \text{ g } C_{10}H_8} = 0.0938 \text{ mol } C_{10}H_8$

$m = \dfrac{0.0938 \text{ mol } C_{10}H_8}{50.0 \text{ g } C_6H_6 \times \dfrac{1 \text{ kg } C_6H_6}{1000 \text{ g } C_6H_6}} = 1.88m \text{ } C_{10}H_8$

$\Delta T_f = K_f \times m = 5.12°C/m \times 1.88m = 9.63°C$

$\Delta T_b = K_b \times m = 2.53°C/m \times 1.88m = 4.76°C$

85. **a.** At 20°C, the solubility of KCl in water is 34.0 g/100 g H_2O, or 44.2 g/130 g H_2O. Therefore, 44.2 g KCl remain dissolved.

b. 50.0 g KCl − 44.2 g KCl = 5.8 g KCl

87. $S = \dfrac{36.0 \text{ g NaCl}}{100 \text{ g } H_2O} \times \dfrac{0.750}{0.750} = \dfrac{27.0 \text{ g NaCl}}{75.0 \text{ g } H_2O}$

The solution contains 26.5 g NaCl/75.0 g H_2O and is therefore unsaturated.

91. $m = \dfrac{\Delta T_f}{K_f} = \dfrac{0.460°C}{5.12°C/m} = 0.898m$

Let x = molar mass of the nondissociating solute.

$\dfrac{5.76 \text{ g}/x}{750 \text{ g benzene}} \times \dfrac{1000 \text{ g benzene}}{1 \text{ kg benzene}} = 0.898m$

$7.68 \text{ g}/x = 0.0898 \text{ mol}$

$x = 7.68 \text{ g}/0.0898 \text{ mol} = 85.5 \text{ g/mol}$

92. $1000 \text{ g } H_2O \times \dfrac{1 \text{ mol}}{18.0 \text{ g } H_2O} = 55.6 \text{ mol } H_2O$

$m_{C_{12}H_{22}O_{11}} = 1.62m = 1.62 \text{ mol } C_{12}H_{22}O_{11}/\text{kg } H_2O$

$X_{H_2O} = \dfrac{55.6 \text{ mol } H_2O}{55.6 \text{ mol } H_2O + 1.62 \text{ mol } C_{12}H_{22}O_{11}} = 0.972$

$X_{C_{12}H_{22}O_{11}} = \dfrac{1.62 \text{ mol } C_{12}H_{22}O_{11}}{55.6 \text{ mol } H_2O + 1.62 \text{ mol } C_{12}H_{22}O_{11}}$

$= 0.0283$

100. $Na_2SO_4(aq) + BaCl(aq) \longrightarrow BaSO_4(s) + 2NaCl(aq)$

$5.28 \text{ g } BaSO_4 \times \dfrac{1 \text{ mol } BaSO_4}{233.4 \text{ g } BaSO_4} \times \dfrac{1 \text{ mol } Na_2SO_4}{1 \text{ mol } BaSO_4}$

$= 0.0226 \text{ mol } Na_2SO_4$

$\text{Molarity} = \dfrac{0.0226 \text{ mol } Na_2SO_4}{250 \times 10^{-3} \text{ L}} = 0.090M \text{ } Na_2SO_4$

103. $V_1 = \dfrac{M_2 \times V_2}{M_1} = \dfrac{0.50M \times 100 \text{ mL}}{2.0M} = 25 \text{ mL}$

Step 1: Start with a stock solution that is 2.0*M* KCl.

Step 2: Transfer 25 mL of 2.0*M* KCl to a 100-mL volumetric flask.

Step 3: Add distilled water up to the 100-mL mark.

108. atomic mass of Rb = (0.72165)(84.912 amu) + (0.27835)(86.909 amu) = 61.277 amu + 24.191 amu = 85.468 amu

114. **a.** 1 mol Fe = 55.8 g Fe

1 mol Cu = 63.5 g Cu

1 mol Hg = 200.6 g Hg

1 mol S = 32.1 g S

b. Each sample contains 6.02×10^{23} atoms.

c. $25.0 \text{ g Fe} \times \dfrac{1 \text{ mol Fe}}{55.8 \text{ g Fe}} = 0.448 \text{ mol Fe}$

$25.0 \text{ g Fe} \times \dfrac{1 \text{ mol Cu}}{63.5 \text{ g Cu}} = 0.394 \text{ mol Cu}$

$25.0 \text{ g Fe} \times \dfrac{1 \text{ mol Hg}}{200.6 \text{ g Hg}} = 0.125 \text{ mol Hg}$

$25.0 \text{ g Fe} \times \dfrac{1 \text{ mol S}}{32.1 \text{ g S}} = 0.779 \text{ mol S}$

115. $1500 \text{ g } H_2 \times \dfrac{1 \text{ mol } H_2}{2.0 \text{ g } H_2} \times \dfrac{22.4 \text{ L } H_2}{1 \text{ mol } H_2} = 1.7 \times 10^4 \text{ L}$

120. $T_1 = 25°C + 273 = 298 \text{ K}$

$T_1 = 45°C + 273 = 318 \text{ K}$

$P_2 = \dfrac{P_1 \times T_2}{T_1} = \dfrac{101.3 \text{ kPa} \times 318 \text{ K}}{298 \text{ K}} = 108 \text{ kPa}$

Chapter 17

1. Heat flows from the system (wax) to the surroundings (air). The process is exothermic.

2. Since the beaker becomes cold, heat is absorbed by the system (chemicals within the beaker) from the surroundings (beaker and surrounding air). The process is endothermic.

3. $\Delta T = 85°C - 21°C = 64°C$

$C_{\text{olive oil}} = \dfrac{q}{m \times \Delta T} = \dfrac{435 \text{ J}}{3.4 \text{ g} \times 64°C} = 2.0 \text{ J/(g} \cdot °C)$

R102 Appendix E

4. $q = C_{Hg} \times m \times \Delta T = (0.14\ J/(g \cdot °C))(250.0\ g)(52°C) = 1800\ J = 1.8\ kJ$

12. $V_{water} = 50.0\ mL + 50.0\ mL = 100.0\ mL$

$m_{water} = 100.0\ \cancel{mL} \times \frac{1.00\ g}{1\ \cancel{mL}} = 100.0\ g$

$\Delta T = 26.0°C - 22.5°C = 3.5°C$

$\Delta H = -q_{surr} = -m_{water} \times C_{water} \times \Delta T = -(100.0\ g) \times (4.18\ J/(g \cdot °C))(3.5°C) = -1460\ J = -1.46\ kJ$

(1.46 kJ of heat was released)

13. $\Delta T = 26.4°C - 25.0°C = 1.4°C$

$\Delta H = -q_{surr} = -m_{water} \times C_{water} \times \Delta T = -(25.0\ g) \times (4.18\ J/(g \cdot °C))(1.4°C) = -150\ J$

(150 J of heat is released by the pebble)

14. $\Delta H = 3.40\ \cancel{mol\ Fe_2O_3} \times \frac{26.3\ kJ}{1\ \cancel{mol\ Fe_2O_3}} = 89.4\ kJ$

15. $\Delta H = 5.66\ \cancel{g\ CS_2} \times \frac{1\ \cancel{mol\ CS_2}}{76.2\ \cancel{g\ CS_2}} \times \frac{89.3\ kJ}{1\ \cancel{mol\ CS_2}} = 6.63\ kJ$

22. $m_{H_2O(s)} = 0.400\ \cancel{kJ} \times \frac{1\ \cancel{mol\ H_2O(s)}}{6.01\ \cancel{kJ}} \times \frac{18.0\ g\ H_2O(s)}{1\ \cancel{mol\ H_2O(s)}} = 1.20\ g\ H_2O(s)$

23. $\Delta H = 50.0\ \cancel{g\ H_2O(l)} \times \frac{1\ \cancel{mol\ H_2O(l)}}{18.0\ \cancel{g\ H_2O(l)}} \times \frac{-6.01\ kJ}{1\ \cancel{mol\ H_2O(l)}} = 16.7\ kJ$

24. $\Delta H = 63.7\ \cancel{g\ H_2O(l)} \times \frac{1\ \cancel{mol\ H_2O(l)}}{18.0\ \cancel{g\ H_2O(l)}} \times \frac{40.7\ kJ}{1\ \cancel{mol\ H_2O(l)}} = 144\ kJ$

25. $\Delta H = 0.46\ \cancel{g\ C_2H_5Cl} \times \frac{1\ \cancel{mol\ C_2H_5Cl}}{64.5\ \cancel{g\ C_2H_5Cl}} \times \frac{24.7\ kJ}{1\ \cancel{mol\ C_2H_5Cl}} = 0.18\ kJ$

26. $\Delta H = 0.677\ \cancel{mol\ NaOH(s)} \times \frac{-44.5\ kJ}{1\ \cancel{mol\ NaOH(s)}} = -30.1\ kJ$

27. moles of $NH_4NO_3(s) = 88.0\ \cancel{kJ} \times \frac{1\ mol\ NH_4NO_3(s)}{25.7\ \cancel{kJ}} = 3.42\ mol\ NH_4NO_3(s)$

35. $\Delta H_f°(\text{reactants}) = 1\ \cancel{mol\ Br_2(g)} \times \frac{30.91\ kJ}{1\ \cancel{mol\ Br_2(g)}} = 30.91\ kJ$

$\Delta H_f°(\text{products}) = 1\ \cancel{mol\ Br_2(l)} \times \frac{0\ kJ}{1\ \cancel{mol\ Br_2(l)}} = 0\ kJ$

$\Delta H° = \Delta H_f°(\text{products}) - \Delta H_f°(\text{reactants}) = 0\ kJ - 30.91\ kJ = -30.91\ kJ$

36. $2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$

$\Delta H_f°(\text{reactants}) = 2\ \cancel{mol\ NO(g)} \times \frac{90.37\ kJ}{1\ \cancel{mol\ NO(g)}} + 1\ \cancel{mol\ O_2(g)} \times \frac{0\ kJ}{1\ \cancel{mol\ O_2(g)}} = 180.7\ kJ$

$\Delta H_f°(\text{products}) = 2\ \cancel{mol\ NO_2(g)} \times \frac{33.85\ kJ}{1\ \cancel{mol\ NO_2(g)}} = 67.70\ kJ$

$\Delta H° = \Delta H_f°(\text{products}) - \Delta H_f°(\text{reactants}) = 67.70\ kJ - 180.7\ kJ = -113.0\ kJ$

47. **a.** exothermic

b. The immediate surroundings are the glass beaker and the air. If one or more of the substances is in water, the water is also considered part of the surroundings.

48. **a.** exothermic **c.** exothermic

b. endothermic **d.** endothermic

51. **a.** $8.50 \times 10^2\ \cancel{cal} \times \frac{1\ Cal}{1000\ \cancel{cal}} = 0.85\ Cal$

b. $444\ \cancel{cal} \times \frac{4.18\ J}{1\ \cancel{cal}} = 1.86 \times 10^3\ J$

c. $1.8\ \cancel{kJ} \times \frac{1000\ J}{1\ \cancel{kJ}} = 1.8 \times 10^3\ J$

d. $45 \times 10^{-1}\ \cancel{kJ} \times \frac{1000\ \cancel{J}}{1\ \cancel{kJ}} \times \frac{1\ cal}{4.18\ \cancel{J}} = 1.1 \times 10^2\ cal$

53. $q = C \times m \times \Delta T = (0.24\ J/\cancel{g} \cdot \cancel{°C})(400.0\ \cancel{g})(45\cancel{°C}) = 4.3 \times 10^3\ J$

59. $\Delta H = 0.75\ \cancel{mol\ Mg} \times \frac{-1204\ kJ}{2\ \cancel{mol\ Mg}} = -4.5 \times 10^2\ kJ$

62. **a.** $\Delta H = 3.50\ \cancel{mol\ H_2O(l)} \times \frac{-6.01\ kJ}{1\ \cancel{mol\ H_2O(l)}} = -21.0\ kJ$

b. $\Delta H = 0.44\ \cancel{mol\ H_2O(g)} \times \frac{-40.7\ kJ}{1\ \cancel{mol\ H_2O(g)}} = -18\ kJ$

c. $\Delta H = 1.25\ \cancel{mol\ NaOH} \times \frac{-44.5\ kJ}{1\ \cancel{mol\ NaOH}} = -55.6\ kJ$

d. $\Delta H = 0.15\ \cancel{mol\ C_2H_6O} \times \frac{5.8\ kJ}{1\ \cancel{mol\ C_2H_6O}} = 6.5\ kJ$

65. **a.** $\Delta H = 1\ \cancel{mol\ Al_2O_3(s)} \times \frac{3352\ kJ}{2\ \cancel{mol\ Al_2O_3(s)}} = 1676\ kJ$

b. ΔH is positive so the reaction is endothermic.

66. Reverse the second equation and change the sign of ΔH. Then add the equations and the values of ΔH.

$Pb(s) + 2Cl_2 \longrightarrow PbCl_4(l) \quad \Delta H = -329.2\ kJ$

$PbCl_2(s) \longrightarrow Pb(s) + Cl_2(g) \quad \Delta H = 359.4\ kJ$

$PbCl_2(s) + Cl_2(g) \longrightarrow PbCl_4(l) \quad \Delta H = 30.2\ kJ$

Selected Solutions **R103**

70. Substance B; for equal masses, the substance with the greater heat capacity undergoes the smaller temperature change.

74. $C_{\text{stainless steel}} = \dfrac{q}{m \times \Delta T} = \dfrac{141\text{ J}}{1.55\text{ g} \times 178^\circ\text{C}} = 0.511\text{ J/(g}\cdot^\circ\text{C)}$

76. a. $\Delta H_f^\circ(\text{reactants}) = 1\text{ mol } CH_4(g) \times \dfrac{-74.86\text{ kJ}}{1\text{ mol } CH_4(g)} + \dfrac{3}{2}\text{ mol } O_2(g) \times \dfrac{0\text{ kJ}}{1\text{ mol } O_2(g)} = -74.86\text{ kJ}$

$\Delta H_f^\circ(\text{products}) = 1\text{ mol } CO(g) \times \dfrac{-110.5\text{ kJ}}{1\text{ mol } CO(g)} + 2\text{ mol } H_2O(l) \times \dfrac{-285.8\text{ kJ}}{1\text{ mol } H_2O(l)} = -682.1\text{ kJ}$

$\Delta H^\circ = \Delta H_f^\circ(\text{products}) - \Delta H_f^\circ(\text{reactants})$
$= (-682.1\text{ kJ}) - (-74.86\text{ kJ}) = -607.2\text{ kJ}$

b. $\Delta H_f^\circ(\text{reactants}) = 2\text{ mol } CO(g) \times \dfrac{-110.5\text{ kJ}}{1\text{ mol } CO(g)} + 1\text{ mol } O_2(g) \times \dfrac{0\text{ kJ}}{1\text{ mol } O_2(g)} = -221.0\text{ kJ}$

$\Delta H_f^\circ(\text{products}) = 2\text{ mol } CO_2(g) \times \dfrac{-393.5\text{ kJ}}{1\text{ mol } CO(g)} = -787.0\text{ kJ}$

$\Delta H^\circ = \Delta H_f^\circ(\text{products}) - \Delta H_f^\circ(\text{reactants})$
$= (-787.0\text{ kJ}) - (-221.0\text{ kJ}) = -566.0\text{ kJ}$

78. Multiply the first equation by 2, reverse it, and change the sign of ΔH.

$2PCl_3(g) + 2Cl_2(g) \longrightarrow 2PCl_5(s) \qquad \Delta H = (2)(-87.9\text{ kJ})$
$2P(s) + 3Cl_2(g) \longrightarrow 2PCl_3(s) \qquad \Delta H = -574\text{ kJ}$
$2P(s) + 5Cl_2(g) \longrightarrow 2PCl_5(s) \qquad \Delta H = -750\text{ kJ}$

81. $q = 106\text{ Cal} \times \dfrac{1000\text{ cal}}{1\text{ Cal}} = 1.06 \times 10^5\text{ cal}$

$\Delta T = 100.0^\circ\text{C} - 25.0^\circ\text{C} = 75.0^\circ\text{C}$

$m_{\text{water}} = \dfrac{q}{C_{\text{water}} \times \Delta T} = \dfrac{1.06 \times 10^5\text{ cal}}{(1.00\text{ cal/(g}\cdot^\circ\text{C))}(75.0^\circ\text{C})} = 1.41 \times 10^3\text{ g}$

85. Calculate the grams of ice that melt when 3.20 kcal is absorbed.

$3.20\text{ kcal} \times \dfrac{4.18\text{ kJ}}{1\text{ kcal}} \times \dfrac{1\text{ mol } H_2O}{6.01\text{ kJ}} \times \dfrac{18.0\text{ g } H_2O}{1\text{ mol } H_2O} = 40.1\text{ g ice melts}$

The amount of ice remaining is:

$1.0\text{ kg} - 0.401\text{ kg} = 0.96\text{ kg ice} = 9.6 \times 10^2\text{ g ice}$

89. a. This equation is the original equation multiplied by 2, so multiply ΔH by 2:

$\Delta H = 2 \times (-92.38\text{ kJ}) = -184.76\text{ kJ}$

b. This equation is the original equation multiplied by $\frac{3}{2}$, so multiply ΔH by $\frac{3}{2}$:

$\Delta H = \dfrac{3}{2} \times (-92.38\text{ kJ}) = -138.6\text{ kJ}$

c. This equation is the original equation multiplied by $\frac{1}{2}$, so multiply ΔH by $\frac{1}{2}$:

$\Delta H = \dfrac{1}{2} \times (-92.38\text{ kJ}) = -46.19\text{ kJ}$

91. a. Calculate the heat absorbed by the melting ice:

$40.0\text{ g } H_2O(l) \times \dfrac{1\text{ mol } H_2O(s)}{18.0\text{ g } H_2O(s)} \times \dfrac{6.01\text{ kJ}}{1\text{ mol } H_2O(l)} \times \dfrac{1000\text{ J}}{1\text{ kJ}} = 1.34 \times 10^4\text{ J}$

Convert to calories:

$1.34 \times 10^4\text{ J} \times \dfrac{1\text{ cal}}{4.18\text{ J}} = 3.21 \times 10^4\text{ cal}$

Convert to kilocalories:

$3.21 \times 10^3\text{ cal} \times \dfrac{1\text{ kcal}}{1000\text{ cal}} = 3.21\text{ kcal}$

b. $m_{\text{water}} = \dfrac{q}{C_{\text{water}} \times \Delta T} = \dfrac{1.34 \times 10^4\text{ J}}{4.18\text{ J/(g}\cdot^\circ\text{C)} \times (25.0^\circ\text{C})} = 128\text{ g}$

94. $\Delta H_f^\circ(\text{reactants}) = 1\text{ mol } C_6H_{12}O_6(s) \times \dfrac{-1260\text{ kJ}}{1\text{ mol } C_6H_{12}O_6(s)} + 6\text{ mol } O_2(g) \times \dfrac{0\text{ kJ}}{1\text{ mol } O_2(g)} = -1260\text{ kJ}$

$\Delta H_f^\circ(\text{products}) = 6\text{ mol } CO_2(g) \times \dfrac{-393.5\text{ kJ}}{1\text{ mol } CO_2(g)} + 6\text{ mol } H_2O(l) \times \dfrac{-285.8\text{ kJ}}{1\text{ mol } H_2O(l)} = -4075.8\text{ kJ}$

$\Delta H^\circ = \Delta H_f^\circ(\text{products}) - \Delta H_f^\circ(\text{reactants}) =$
$(-4075.8\text{ kJ}) - (-1260\text{ kJ}) = -2820\text{ kJ}$

97. The heat released as the glass cools equals the heat absorbed by the water.

$q_{\text{glass}} = -q_{\text{water}}$ and $T_{f,\text{glass}} = T_{f,\text{water}} = T_f$, so:

$C_{\text{glass}}m_{\text{glass}}(T_f - T_{i,\text{glass}}) = -C_{\text{water}}m_{\text{water}}(T_f - T_{i,\text{water}})$

$T_f(C_{\text{glass}}m_{\text{glass}} + C_{\text{water}}m_{\text{water}}) = C_{\text{water}}m_{\text{water}}T_{i,\text{water}} + C_{\text{glass}}m_{\text{glass}}T_{i,\text{glass}}$

$T_f = \dfrac{C_{\text{water}}m_{\text{water}}T_{i,\text{water}} + C_{\text{glass}}m_{\text{glass}}T_{i,\text{glass}}}{C_{\text{glass}}m_{\text{glass}} + C_{\text{water}}m_{\text{water}}} =$

$\dfrac{(1.00\text{ cal/(g}\cdot^\circ\text{C))}(175\text{ g})(21^\circ\text{C}) + (2.1\text{ cal/(g}\cdot^\circ\text{C))}(41.0\text{ g})(95^\circ\text{C})}{(2.1\text{ cal/(g}\cdot^\circ\text{C))}(41.0\text{ g}) + (1.00\text{ cal/(g}\cdot^\circ\text{C))}(175\text{ g})}$

$= \dfrac{3700\text{ cal} + 8200\text{ cal}}{86\text{ cal/°C} + 175\text{ cal/°C}} = \dfrac{11900\text{ cal}}{261\text{ cal/°C}} = 45.6^\circ\text{C}$

R104 Appendix E

102. Evaporation is an endothermic process. As the water evaporates, it absorbs heat from the trees and fruit, causing their temperature to decrease. This can lead to the branches, leaves and fruit freezing.

106. **a.** 6.99 m **c.** 3.6×10^2 m/s
b. 10.68 g **d.** 4.44°C

b. favors reactants **d.** favors reactants

18. **a.** favors reactants **c.** favors products
b. favors reactants **d.** favors products

19. $K_{eq} = \frac{[NH_3]^2}{[N_2][H_2]^3} = \frac{(0.10M)^2}{(0.25M) \times (0.15M)^3} = 12$

20. $K_{eq} = \frac{[N_2][H_2]^3}{[NH_3]^2} = \frac{(0.25M) \times (0.15M)^3}{(0.10M)^2} = 8.4 \times 10^{-2};$
One is the inverse of the other.

21. $K_{eq} = \frac{[NO]^2}{[N_2][O_2]} = \frac{(0.02M)^2}{0.50M \times 0.50M} = 1.6 \times 10^{-3}$

22. $0.047 \cancel{\text{ mol H}_2\text{O}} \times \frac{1 \text{ mol H}_2}{1 \cancel{\text{ mol H}_2\text{O}}} = 0.047 \text{ mol H}_2$
$0.10 - 0.047 = 0.053 \text{ mol H}_2$ at equilibrium
$(\text{mol H}_2 = \text{mol CO}_2)$
$K_{eq} = \frac{[H_2O][CO]}{[H_2][CO_2]} = \frac{(0.047\cancel{M}) \times (0.047\cancel{M})}{(0.053\cancel{M}) \times (0.053\cancel{M})} = 0.79$

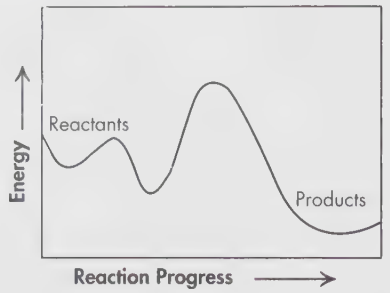
23. $K_{eq} = \frac{[N_2O_4]}{[NO_2]^2}$
$5.6 = \frac{0.66M}{[NO_2]^2}$
$[NO_2]^2 = \frac{0.66M}{5.6}$
$[NO_2] = \sqrt{\frac{0.66M}{5.6}} = 0.34M$

24. $[H_2] = [I_2] = 0.50M;$
$K_{eq} = \frac{[H_2][I_2]}{[HI]^2}$
$0.020 = \frac{0.50M \times 0.50M}{[HI]^2}$
$[HI]^2 = \frac{0.50M \times 0.50M}{0.020} = \frac{0.25M^2}{0.020} = 12.5M^2$
$[HI] = \sqrt{12.5M^2} = 3.5M$

33. $K_{sp} = [Pb^{2+}] \times [S^{2-}]$
$3.0 \times 10^{-28} = [Pb^{2+}]^2$
$[Pb^{2+}] = \sqrt{3.0 \times 10^{-28}M^2} = 2 \times 10^{-14}M$

34. $K_{sp} = [Ca^{2+}] \times [CO_3^{2-}]$
$4.5 \times 10^{-9} = [Ca^{2+}]^2$
$[Ca^{2+}] = \sqrt{4.5 \times 10^{-9}M^2} = 6.7 \times 10^{-5}M$

35. $K_{sp} = [Pb^{2+}] \times [S^{2-}]$
$[S^{2-}] = \frac{K_{sp}}{[Pb^{2+}]} = \frac{(8 \times 10^{-19})}{0.04} = 2 \times 10^{-17}M$



36. $K_{sp} = [Sr^{2+}] \times [SO_4^{2-}]$
$[SO_4^{2-}] = \frac{K_{sp}}{[Sr^{2+}]} = \frac{(3.2 \times 10^{-7})}{0.10} = 3.2 \times 10^{-6}M$

54. Atoms, ions, or molecules can react to form products, or they can bounce apart unchanged.

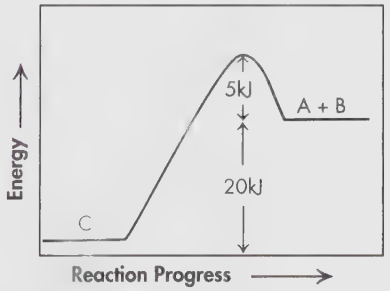
58. A catalyst increases the rate of reactions by providing an alternative reaction mechanism with a lower activation energy.

Selected Solutions **R105**

61.

The intermediate is $N_2O_2(g)$.

66. a. $K_{eq} = \dfrac{[CH_4] \times [H_2S]^2}{[H_2]^4 \times [CS_2]}$



b. $K_{eq} = \dfrac{[PCl_3] \times [Cl_2]}{[PCl_5]}$

71. c, b, d, a

77. a. Entropy increases. b. Entropy decreases.

81. c

85. Since the total energy change for the forward reaction (−20 kJ) is negative, energy is released, and the reaction is exothermic. The reverse reaction is endothermic (energy is absorbed). The reaction progress curve for the reverse reaction is as follows:

The activation energy of the reverse reaction is the total height of the peak (20 kJ + 5 kJ = 25 kJ).

89. increase in products

91. $K_{eq} = \dfrac{[CO] \times [H_2O]}{[CO_2] \times [H_2]} = \dfrac{0.448 \times 0.448}{0.552 \times 0.552} = 6.59 \times 10^{-1}$

92. The product of the concentrations of the ions must be greater than the ion-product constant (K_{sp}).

97. a. favors products c. favors reactants

b. no effect d. no effect

100. a. IO^-

b. two

c. the slow reaction

d. $2H_2O_2 \longrightarrow 2H_2O + O_2$

e. No, the I^- is changed in the reaction. A catalyst would not appear in the reaction as a reactant, an intermediate, or a product.

103. first order in NO_2^-, first order in NH_4^+, second order overall

105. Increase pressure, cool the reaction mixture, and remove NH_3

109. a. about 3 g

b. about 1.3 g

c. The rate of decomposition slows down over time.

115. Potassium chloride is an ionic compound, not a molecular compound.

117. a. sodium perchlorate, 1−

b. potassium permanganate, 1−

c. calcium phosphate, 3−

d. magnesium carbonate, 2−

e. sodium sulfate, 2−

f. potassium dichromate, 2−

121. a. $2KClO_3(s) + \text{heat} \longrightarrow 2KCl(s) + 3O_2(g)$

b. molar mass = 39.1 + 35.5 + (3 × 16.0) = 122.6 g

$$4.88 \text{ g } \cancel{KClO_3} \times \frac{1 \text{ } \cancel{\text{mol } KClO_3}}{122.6 \text{ g } \cancel{KClO_3}} \times \frac{3 \text{ } \cancel{\text{mol } O_2}}{2 \text{ } \cancel{\text{mol } KClO_3}} \times \frac{32 \text{ g } O_2}{1 \text{ } \cancel{\text{mol } O_2}} = 1.91 \text{ g } O_2$$

129. $2.40 \text{ } \cancel{\text{L KCl}} \times \dfrac{0.66 \text{ mol KCl}}{1 \text{ } \cancel{\text{L KCl}}} = 1.58 \text{ mol KCl}$

133. The process is exothermic because heat is released.

Chapter 19

1. a. H^+ is the Lewis acid; H_2O is the Lewis base.

b. $AlCl_3$ is the Lewis acid; Cl^- is the Lewis base.

2. Lewis base; it has a nonbonding pair of electrons that it can donate.

10. a. basic c. acidic

b. basic d. neutral

b. redox reaction: H_2 is oxidized (0 to +1), Cu is reduced (+2 to 0)

23. **a.**

$$\overset{\overset{(1)(-6) = -6}{\overbrace{\quad\quad}}}{\overset{+1\ +5\ -2}{KClO_3(s)} \longrightarrow \overset{+1\ -1}{KCl(s)} + \overset{0}{O_2(g)}}$$

$$\underbrace{\quad\quad}_{(3)(+2) = +6}$$

One K atom must be reduced for every 3 oxygen atoms oxidized.

$KClO_3(s) \longrightarrow KCl(s) + O_2(g)$

Balance by inspection; put the coefficient 3 in front of O_2, and the coefficient 2 in front of $KClO_3$ and KCl:

$2KClO_3(s) \longrightarrow 2KCl(s) + 3O_2(g)$

b. $2HNO_2(aq) + 2HI(aq) \longrightarrow 2NO(g) + I_2(s) + 2H_2O(l)$

24. **a.**

$$\overset{\overset{(2)(-3) = -6}{\overbrace{\quad\quad\quad\quad}}}{\overset{+3\ -2}{Bi_2S_3(s)} + \overset{+1\ +5\ -2}{HNO_3(aq)} \longrightarrow \overset{+3\ +5\ -2}{Bi(NO_3)_3(aq)} + \overset{+2\ -2}{NO(g)} + \overset{0}{S(s)} + \overset{+1\ -2}{H_2O(l)}}$$

$$\underbrace{\quad\quad\quad\quad}_{(3)(+2) = +6}$$

2 N atoms must be reduced for every 3 sulfur atoms oxidized.

$Bi_2S_3(s) + 2HNO_3(aq) \longrightarrow Bi(NO_3)_3(aq) + 2NO(g) + 3S(s) + H_2O(l)$

Balance by inspection; put the coefficient 2 in front of $Bi(NO_3)_3$, the coefficient 8 in front of HNO_3, and the coefficient 4 in front of H_2O:

$Bi_2S_3(s) + 8HNO_3(aq) \longrightarrow 2Bi(NO_3)_3(aq) + 2NO(g) + 3S(s) + 4H_2O(l)$

b. $SbCl_5(aq) + 2KI(aq) \longrightarrow SbCl_3(aq) + 2KCl(aq) + I_2(s)$

R108 Appendix E

25. Oxidation half-reaction: $\overset{+2}{Sn}^{2+} \longrightarrow \overset{+4}{Sn}^{4+}$

Reduction half-reaction: $\overset{+6}{Cr_2O_7}^{2-} \longrightarrow \overset{+3}{Cr}^{3+}$

Oxidation: $Sn^{2+}(aq) \longrightarrow Sn^{4+}(aq)$ (atoms balanced)

Reduction: $Cr_2O_7^{2-}(aq) + 14H^+ \longrightarrow 2Cr^{3+}(aq) + 7H_2O(l)$ (atoms balanced)

Oxidation: $Sn^{2+}(aq) \longrightarrow Sn^{4+}(aq) + 2e^-$ (charges balanced)

Reduction: $Cr_2O_7^{2-}(aq) + 14H^+ + 6e^- \longrightarrow 2Cr^{3+}(aq) + 7H_2O(l)$ (charges balanced)

Oxidation: $3Sn^{2+}(aq) \longrightarrow 3Sn^{4+}(aq) + 6e^-$

Reduction: $Cr_2O_7^{2-}(aq) + 14H^+ + 6e^- \longrightarrow 2Cr^{3+}(aq) + 7H_2O(l)$

$3Sn^{2+}(aq) + Cr_2O_7^{2-}(aq) + 14H^+ + \cancel{6e^-} \longrightarrow 3Sn^{4+}(aq) + \cancel{6e^-} + 2Cr^{3+}(aq) + 7H_2O(l)$

$3Sn^{2+}(aq) + Cr_2O_7^{2-}(aq) + 14H^+ \longrightarrow 3Sn^{4+}(aq) + 2Cr^{3+}(aq) + 7H_2O(l)$

26. $Zn(s) + NO_3^-(aq) + H_2O(l) + OH^-(aq) \longrightarrow Zn^{2+} + OH^-(aq) + NH_3(aq)$

Oxidation half-reaction: $\overset{0}{Zn} \longrightarrow \overset{+2}{Zn}^{2+}$

Reduction half-reaction: $\overset{+5}{NO_3}^- \longrightarrow \overset{-3}{NH_3}$

Oxidation: $Zn(s) \longrightarrow Zn^{2+}(aq)$ (atoms balanced)

Reduction: $NO_3^-(aq) + 9H^+ + 9OH^-(aq) \longrightarrow NH_3(aq) + 3H_2O(l) + 9OH^-(aq)$ (atoms balanced)

Oxidation: $Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^-$ (charges balanced)

Reduction: $NO_3^-(aq) + 9H^+ + 9OH^-(aq) + 8e^- \longrightarrow NH_3(aq) + 3H_2O(l) + 9OH^-(aq)$ (charges balanced)

Oxidation: $Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^-$ (charges balanced)

Reduction: $NO_3^-(aq) + 9H_2O(l) + 8e^- \longrightarrow NH_3(aq) + 3H_2O(l) + 9OH^-(aq)$ (charges balanced)

Oxidation: $4Zn(s) \longrightarrow 4Zn^{2+}(aq) + 8e^-$ (charges balanced)

Reduction: $NO_3^-(aq) + 9H_2O(l) + 8e^- \longrightarrow NH_3(aq) + 3H_2O(l) + 9OH^-(aq)$ (charges balanced)

$4Zn(s) + NO_3^-(aq) + 9H_2O(l) + \cancel{8e^-} \longrightarrow 4Zn^{2+}(aq) + \cancel{8e^-} + NH_3(aq) + 3H_2O + 9OH^-(aq)$

$4Zn(s) + NO_3^-(aq) + 6H_2O(l) \longrightarrow 4Zn^{2+}(aq) + NH_3(aq) + 9OH^-(aq)$

$4Zn(s) + NO_3^-(aq) + 6H_2O(l) + 16OH^-(aq) \longrightarrow 4Zn^{2+}(aq) + NH_3(aq) + 9OH^-(aq) + 16OH^-(aq)$ (spectator ions added)

$4Zn(s) + NO_3^-(aq) + 6H_2O(l) + 16OH^-(aq) \longrightarrow 4Zn(OH)_4^{2-}(aq) + NH_3(aq) + 9OH^-(aq)$

$4Zn(s) + NO_3^-(aq) + 6H_2O(l) + 7OH^-(aq) \longrightarrow 4Zn(OH)_4^{2-}(aq) + NH_3(aq)$

34. **a.** $2Ba(s) + O_2(g) \longrightarrow 2BaO(s)$; barium is oxidized

b. $CuO(s) + H_2(g) \longrightarrow Cu(s) + H_2O(l)$; copper is reduced

c. $C_2H_4(g) + 3O_2(g) \longrightarrow 2CO_2(g) + 2H_2O(l)$; carbon is oxidized

d. $3CaO(s) + 2Al(s) \longrightarrow Al_2O_3(s) + 3Ca(s)$; calcium is reduced

36. **a.** oxidizing agent **c.** oxidizing agent

b. reducing agent **d.** oxidizing agent

37. **a.** H_2 is oxidized; S is reduced.

b. N_2 is reduced; H_2 is oxidized.

c. S is oxidized; O_2 is reduced.

d. H_2 is oxidized; O_2 is reduced.

42. **a.** O, −2; H, +1 **d.** H, +1; P, +5; O, −2

b. P, +5; O, −2 **e.** H, +1; S, +6; O, −2

c. I, +5; O, −2

44. **a.** $2Al(s) + 3Cl_2(g) \longrightarrow 2AlCl_3(s)$

b. $2Al(s) + Fe_2O_3(s) \longrightarrow Al_2O_3(s) + 2Fe(s)$

c. $3Cl_2(g) + 6KOH(aq) \longrightarrow KClO_3(aq) + 5KCl(aq) + 3H_2O(l)$

d. $2HNO_3(aq) + 3H_2S(aq) \longrightarrow 3S(s) + 2NO(g) + 4H_2O(l)$

e. $KIO_4(aq) + 7KI(aq) + 8HCl(aq) \longrightarrow 8KCl(aq) + 4I_2(s) + 4H_2O(l)$

45. redox: a, b, c, d, e

46. **a.** $CuS(s) + 8NO_3^-(aq) + 8H^+(aq) \longrightarrow Cu(NO_3)_2(aq) + SO_2(g) + 6NO_2(g) + 4H_2O(l)$

b. $6I^-(aq) + 2NO_3^-(aq) + 8H^+(aq) \longrightarrow 3I_2(s) + 2NO(g) + 4H_2O(l)$

47. **a.** $MnO_4^-(aq) + ClO_2^-(aq) \longrightarrow MnO_2(s) + ClO_4^-(aq)$

b. $Cr^{3+}(aq) + ClO^-(aq) \longrightarrow CrO_4^{2-}(aq) + Cl^-(aq)$

c. $Mn^{3+}(aq) + I^-(aq) \longrightarrow Mn^{2+}(aq) + IO_3^-(aq)$

50. **a.** +4 **b.** +5 **c.** +5 **d.** +3 **e.** +5 **f.** +3

54. **a.** $16H^+(aq) + 2Cr_2O_7^{2-}(aq) + C_2H_5OH(aq) \longrightarrow 4Cr^{3+}(aq) + 2CO_2(g) + 11H_2O(l)$

b. oxidizing agent

59. **a.** $Ba(ClO_3)_2(s) \longrightarrow BaCl_2(s) + 3O_2(g)$

b. $2PbS(s) + 3O_2(g) \longrightarrow 2PbO(s) + 2SO_2(g)$

63. $1s^22s^22p^63s^23p^5$; a chlorine atom can "lose" its 7 valence electrons or it can gain 1 electron to fill the last 3*p* orbital.

Selected Solutions **R109**

66. In every redox reaction one species loses one or more electrons and is a reducing agent. Another substance gains one or more electrons and is an oxidizing agent.

70. **a.** $Rb(s) + I_2(s) \longrightarrow RbI_2(s)$; oxidizing agent is I

b. $Ba(s) + 2H_2O(l) \longrightarrow Ba(OH)_2(aq) + H_2(g)$; oxidizing agent is H

c. $2Al(s) + 3FeSO_4(aq) \longrightarrow Al_2(SO_4)_3(aq) + 3Fe(s)$; oxidizing agent is Fe

d. $C_4H_8(g) + 6O_2(g) \longrightarrow 4CO_2(g) + 4H_2O(l)$; oxidizing agent is O

e. $Zn(s) + 2HBr(aq) \longrightarrow ZnBr_2(aq) + H_2(g)$; oxidizing agent is H

f. $Mg(s) + Br_2(l) \longrightarrow MgBr_2(s)$, oxidizing agent is Br

73. $2AgNO_3(aq) + Cu(s) \longrightarrow Cu(NO_3)_2(aq) + 2Ag(s)$

$$85.0\ \cancel{mL} \times \frac{1\ \cancel{L}}{1000\ \cancel{mL}} \times \frac{0.150\ \cancel{mol\ AgNO_3}}{1\ \cancel{L\ AgNO_3}} \times \frac{1\ \cancel{mol\ Cu}}{2\ \cancel{mol\ AgNO_3}} \times \frac{63.5\ g\ Cu}{1\ \cancel{mol\ Cu}} = 0.405\ g\ Cu$$

80. **a.** $Cr_2O_7^{2-}(aq) + 14H^+ + 6e^- \longrightarrow 2Cr^{3+}(aq) + 7H_2O(l)$

$Cr_2O_7^{2-}$ is an oxidizing agent.

b. $S_2O_3^{2-}(aq) + 5H_2O(l) \longrightarrow 2SO_4^{2-}(aq) + 10H^+ + 4e^-$

$S_2O_3^{2-}$ is a reducing agent.

SO_4^{2-} is an oxidizing agent.

c. $CrO_4^{2-}(aq) + 4H_2O(l) + 3e^- \longrightarrow Cr(OH)_3(aq) + 5OH^-(aq)$

CrO_4^{2-} is an oxidizing agent.

d. $MnO_4^-(aq) + 8H^+ + 5e^- \longrightarrow Mn^{2+}(aq) + 4H_2O(l)$

MnO_4^- is an oxidizing agent.

e. $C_2O_4^{2-}(aq) \longrightarrow 2CO_2(g) + 2e^-$

$C_2O_4^{2-}$ is a reducing agent.

f. $2H_2O(l) + MnO_4^-(aq) + 3e^- \longrightarrow MnO_2(s) + 4OH^-(aq)$

MnO_4^- is an oxidizing agent.

86. **a.**

Alkane burned	O_2 used (mol)	CO_2 produced (mol)	H_2O produced (mol)
CH_4	2	1	2
C_2H_6	3.5	2	3
C_3H_8	5	3	4
C_4H_{10}	6.5	4	5
C_5H_{12}	8	5	6
C_6H_{14}	9.5	6	7

b. $C_xH_y + [x + (y/4)]O_2 \longrightarrow xCO_2 + (y/2)H_2O$

88. $T = 25°C + 273 = 298\ K$

$$P = \frac{n \times R \times T}{V} = \frac{\left(13.8\ \cancel{g\ N_2} \times \frac{1\ \cancel{mol\ N_2}}{28.0\ \cancel{g\ N_2}}\right) \times 8.31 \left(\frac{\cancel{L} \cdot kPa}{\cancel{K} \cdot \cancel{mol}}\right) \times 298\ \cancel{K}}{6.8\ \cancel{L}} = 1.8 \times 10^2\ kPa$$

91. $V_2 = \frac{M_1 \times V_1}{M_2} = \frac{1.5\cancel{M\ HCl} \times 440\ mL\ HCl}{6.0\cancel{M\ HCl}} = 110\ mL\ 6.0M\ HCl$

Dilute 110 mL of 6.0*M* HCl to 440 mL total volume.

94. $PbBr_2(s) \longrightarrow Pb^{2+} + 2Br^-$

$K_{sp} = [Pb^{2+}][Br^-] = 2.1 \times 10^{-6}$

Let $x = [Pb^{2+}]$.

Then $2x = [Br^-]$.

$(x)(2x)^2 = 2.1 \times 10^{-6}$

$4x^3 = 2.1 \times 10^{-6}$

$x = [Pb^{2+}] = 8.1 \times 10^{-3}$

The solubility of $PbBr_2$ is $8.1 \times 10^{-3}M$.

100. **a.** $pH = -\log[H^+] = -\log(0.000010) = -\log(10^{-5}) = 5.00$ (acidic)

b. $[H^+] = \frac{K_w}{[OH^-]} = \frac{1.0 \times 10^{-14}M^2}{1 \times 10^{-4}M} = 1.0 \times 10^{-10}M$

$pH = -\log[H^+] = -\log(1.0 \times 10^{-10}M) = 10.00$ (basic)

c. $[H^+] = \frac{K_w}{[OH^-]} = \frac{1.0 \times 10^{-14}M^2}{1 \times 10^{-1}M} = 1.0 \times 10^{-13}M$

$pH = -\log[H^+] = -\log(1.0 \times 10^{-13}M) = 13.00$ (basic)

d. $pH = -\log[H^+] = -\log(3.0 \times 10^{-7}) = 6.50$ (acidic)

Chapter 21

8. The half-reactions are

Oxidation: $Cr(s) \longrightarrow Cr^{3+}(aq) + 3e^-$

Reduction: $Zn^{2+}(aq) + 2e^- \longrightarrow Zn(s)$

Writing both half-cells as reductions:

$Cr^{3+}(aq) + 3e^- \longrightarrow Cr(s)$ $\quad E°_{Cr^{3+}} = -0.74\ V$

$Zn^{2+}(aq) + 2e^- \longrightarrow Zn(s)$ $\quad E°_{Zn^{2+}} = -0.76\ V$

$E°_{cell} = E°_{red} - E°_{oxid} = E°_{Zn^{2+}} - E°_{Cr^{3+}}$

$= -0.76\ V - (-0.74\ V) = -0.02\ V$

$E°_{cell} < 0$, so the reaction is not spontaneous.

R110 Appendix E

9. The half-reactions are

Oxidation: $Fe(s) \longrightarrow Fe^{2+}(aq) + 2e^-$

Reduction: $Co^{2+}(aq) + 2e^- \longrightarrow Co(s)$

Writing both half-cells as reductions:

$Fe^{2+}(aq) + 2e^- \longrightarrow Fe(s) \qquad E°_{Fe^{2+}} = -0.44\ V$

$Co^{2+}(aq) + 2e^- \longrightarrow Co(s) \qquad E°_{Co^{2+}} = -0.28\ V$

$E°_{cell} = E°_{red} - E°_{oxid} = E°_{Co^{2+}} - E°_{Fe^{2+}}$

$= -0.28\ V - (-0.44\ V) = +0.16\ V$

$E°_{cell} > 0$, so the reaction is spontaneous.

10. Cu^{2+} is reduced, and Al is oxidized.

Oxidation: $Al(s) \longrightarrow Al^{3+}(aq) + 3e^-$

Reduction: $Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s)$

Writing both half-cells as reductions:

$2[Al(s) \longrightarrow Al^{3+}(aq) + 3e^-]$

$3[Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s)]$

$2Al(s) \longrightarrow 2Al^{3+}(aq) + \cancel{6e^-}$

$3Cu^{2+}(aq) + \cancel{6e^-} \longrightarrow 3Cu(s)$

$2Al(s) + 3Cu^{2+}(aq) \longrightarrow 2Al^{3+}(aq) + 3Cu(s)$

11. Ag^+ is reduced, and Cu is oxidized.

The half-reactions are

Oxidation: $Cu(s) \longrightarrow Cu^{2+}(aq) + 2e^-$

Reduction: $Ag^+(aq) + e^- \longrightarrow Ag(s)$

Writing both half-cells as reductions:

$Cu(s) \longrightarrow Cu^{2+}(aq) + 2e^-$

$2[Ag^+(aq) + e^- \longrightarrow Ag(s)]$

$Cu(s) \longrightarrow Cu^{2+}(aq) + \cancel{2e^-}$

$2Ag^{2+}(aq) + \cancel{2e^-} \longrightarrow 2Ag(s)$

$Cu(s) + 2Ag^{2+}(aq) \longrightarrow Cu^{2+}(aq) + 2Ag(s)$

12. $E°_{cell} = E°_{red} - E°_{oxid} = E°_{Cu^{2+}} - E°_{Al^{3+}}$

$= 0.34\ V - (-1.66\ V) = +2.00\ V$

13. $E°_{cell} = E°_{red} - E°_{oxid} = E°_{Ag^+} - E°_{Cu^{2+}}$

$= 0.80\ V - (+0.34\ V) = +0.46\ V$

28. Using Table 21.1, the more active element is the most readily oxidized.

a. Cu **b.** Ca **c.** Mg **d.** Sn **e.** Zn **f.** Al

33. A zinc container (anode) filled with electrolyte paste; the cathode is a graphite rod embedded in the paste; Zn is oxidized; MnO_2 is reduced.

36. $Pb(s) \mid PbSO_4(aq) \parallel PbO_2(s) \mid PbSO_4(s)$

40. The standard reduction potential of a half-cell is a measure of the tendency of a given half-reaction to occur as a reduction under standard conditions. The difference between the standard reduction potentials of the two half-cells is called the standard cell potential.

44. **a.** Cu is oxidized, and H^+ is reduced.

Writing both half-reactions as reductions:

$Cu(s) \longrightarrow Cu^{2+}(aq) + 2e^- \qquad E°_{Cu^{2+}} = +0.34\ V$

$2H^+(aq) + 2e^- \longrightarrow H_2(g) \qquad E°_{H^+} = 0.000\ V$

$E°_{cell} = E°_{red} - E°_{oxid} = E°_{H^+} - E°_{Cu^{2+}}$

$= 0.000\ V - (+0.34\ V) = -0.34\ V$

$E°_{cell} < 0$, so the reaction will not occur spontaneously.

b. Ag is oxidized, and Fe^{2+} is reduced.

Writing both half-reactions as reductions:

$Ag(s) \longrightarrow Ag^+(aq) + e^- \qquad E°_{Ag^+} = +0.80\ V$

$Fe^{2+}(aq) + 2e^- \longrightarrow Fe(s) \qquad E°_{Fe^{2+}} = -0.44\ V$

$E°_{cell} = E°_{red} - E°_{oxid} = E°_{Fe^{2+}} - E°_{Ag^+}$

$= -0.44\ V - (+0.80\ V) = -1.24\ V$

$E°_{cell} < 0$, so the reaction will not occur spontaneously.

46. Voltaic cells convert chemical energy into electrical energy. Electrolytic cells use electrical energy to cause a chemical reaction.

50. Chloride ions are oxidized to produce chlorine gas, and water is reduced to produce hydrogen gas.

55. The iron nail will become copper-plated as Fe is oxidized to Fe^{2+} and Cu^{2+} is reduced to Cu.

Oxidation: $Fe(s) \longrightarrow Fe^{2+}(aq) + \cancel{2e^-}$

Reduction: $Cu^{2+}(aq) + \cancel{2e^-} \longrightarrow Cu(s)$

Overall cell reaction:

$Fe(s) + Cu^{2+}(aq) \longrightarrow Fe^{2+}(aq) + Cu(s)$

57. **a.** $Sn(s) + Pb^{2+}(aq) \longrightarrow Sn^{2+}(aq) + Pb(s)$

Oxidation: $Sn(s) \longrightarrow Sn^{2+}(aq) + \cancel{2e^-}$

Reduction: $Pb^{2+}(aq) + \cancel{2e^-} \longrightarrow Pb(s)$

Overall cell reaction:

$Sn(s) + Pb^{2+}(aq) \longrightarrow Sn^{2+}(aq) + Pb(s)$

$E°_{cell} = E°_{red} - E°_{oxid} = E°_{Pb^{2+}} - E°_{Sn^{2+}}$

$= -0.13\ V - (-0.14\ V) = +0.01\ V$

b. $H_2(g) + Br_2(l) \longrightarrow 2H^+(aq) + 2Br^-(aq)$

Oxidation: $H_2(g) \longrightarrow 2H^+(aq) + \cancel{2e^-}$

Reduction: $Br_2(l) + \cancel{2e^-} \longrightarrow 2Br^-(aq)$

Overall cell reaction:

$H_2(g) + Br_2(l) \longrightarrow 2H^+(aq) + 2Br^-(aq)$

$E°_{cell} = E°_{red} - E°_{oxid} = E°_{Br^-} - E°_{H^+}$

$= +1.07\ V - 0.00\ V = +1.07\ V$

60. If the cell potential for a redox reaction is positive, the reaction is spontaneous as written.

Selected Solutions **R111**

62. **a.** oxidation: $2Cl^-(l) \longrightarrow Cl_2(g) + 2e^-$ (at anode)

reduction: $Al^{3+}(l) + 3e^- \longrightarrow Al(l)$ (at cathode)

b. Multiply the oxidation half-reaction by 3 and the reduction half-reaction by 2 to balance the electrons:

$6Cl^-(l) \longrightarrow 3Cl_2(g) + \cancel{6e^-}$

$2Al^{3+}(l) + \cancel{6e^-} \longrightarrow 2Al(l)$

Overall cell reaction:

$2AlCl_3(l) \longrightarrow 2Al(l) + 3Cl_2(g)$

c. Chlorine gas is produced at the anode. Liquid aluminum is produced at the cathode.

68. **a.** Possible oxidation reactions at anode:

(*i*) $2Cl^-(aq) \longrightarrow Cl_2(g) + 2e^-$

(*ii*) $2H_2O(l) \longrightarrow O_2(g) + 4H^+(aq) + 4e^-$

b. Possible reduction reactions at cathode:

(*i*) $Na^+(aq) + e^- \longrightarrow Na(s)$

(*ii*) $2H_2O(l) + 2e^- \longrightarrow H_2(g) + 2OH^-(aq)$

c. (*i*) Chloride ions are more readily oxidized to chlorine gas than water molecules are oxidized to oxygen.

d. (*ii*) Water molecules are more easily reduced than sodium ions.

69. The stronger oxidizing agent will have the more positive standard reduction potential ($E°$).

a. Ca^{2+} **b.** Hg_2^{2+} **c.** Cu^+ **d.** Hg^{2+}

71. A direct current flows in one direction only. If an alternating current is used, the reactions at the anode and cathode would constantly be reversed.

73. The cathode reaction in a dry cell is not reversible, so dry cells are not rechargeable. The anode and cathode reactions in a lead storage battery are reversible. Therefore, lead storage batteries are rechargeable when electrical energy is applied.

75. The spoon is being electroplated with silver in an electrolytic cell. The spoon serves as the cathode, and the anode is metallic silver. The electrolyte is a solution of silver cyanide. When a direct current is applied, silver ions move from the anode to the spoon, where they are reduced to silver metal.

79. d; the voltage of a dry cell decreases steadily.

80. **a.** The standard reduction potential for AgCl (+0.22 V) is more positive than the standard reduction potential for Ni^{2+} (−0.25 V), so AgCl is reduced and Ni is oxidized.

Oxidation: $Ni(s) \longrightarrow Ni^{2+}(aq) + 2e^-$

Reduction: $2[AgCl(s) + e^- \longrightarrow Ag(s) + Cl^-(aq)]$

Overall cell reaction:

$Ni(s) + 2AgCl(s) \longrightarrow 2Ag(s) + NiCl_2(aq)$

$E°_{cell} = E°_{red} - E°_{oxid} = E°_{AgCl} - E°_{Ni^{2+}}$

$= +0.22\ V - (-0.25\ V) = +0.47\ V$

b. The standard reduction potential for Cl^- (+1.36 V) is more positive than the standard reduction potential for Al^{3+} (−1.66 V), so Cl^- is reduced and Al^{3+} is oxidized.

Oxidation: $2[Al(s) \longrightarrow Al^{3+}(aq) + 3e^-]$

Reduction: $3[Cl_2(g) + 2e^- \longrightarrow 2Cl^-(aq)]$

Overall cell reaction:

$2Al(s) + 3Cl_2(s) \longrightarrow 2AlCl_3(s)$

$E°_{cell} = E°_{red} - E°_{oxid} = E°_{Cl^-} - E°_{Al^{3+}}$

$= +1.36\ V - (-1.66\ V) = +3.02\ V$

84. The battery output would not be 12 V.

88. Connect the positive electrode of the power source to the gold object and the negative electrode to another metal. The gold object will then serve as the anode and the gold will be oxidized.

91. $T_1 = 30°C + 273 = 303\ K$

$T_2 = 60°C + 273 = 333\ K$

$$V_2 = \frac{V_1 \times T_2}{T_1} = \frac{425\ mL \times 333\ \cancel{K}}{303\ \cancel{K}} = 467\ mL$$

93. **a.** $$250\ \cancel{g} \times \frac{0.90\ g\ NaCl}{100\ \cancel{g}} = 2.3\ g\ NaCl$$

b. $$500\ \cancel{mL} \times \frac{1\ \cancel{L}}{1000\ \cancel{mL}} \times \frac{2\ \cancel{mol\ KNO_3}}{1\ \cancel{L}} \times \frac{101.1\ g\ KNO_3}{1\ \cancel{mol\ KNO_3}} = 101\ g\ KNO_3$$

97. $$4.80\ \cancel{g\ CH_4} \times \frac{1\ \cancel{mol\ CH_4}}{16.0\ \cancel{g\ CH_4}} \times \frac{-890\ kJ}{1\ \cancel{mol\ CH_4}} = -267\ kJ$$

98. a and c; $K_{eq} < 1$

100. **a.** $pH = -\log[H^+] = -\log(1.0 \times 10^{-8}M) = 8.00$

b. $pH = -\log[H^+] = -\log(0.000010M) = 5.00$

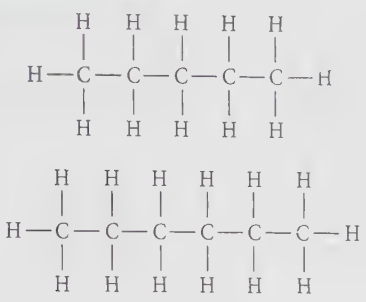
c. $$[H^+] = \frac{K_w}{[OH^-]} = \frac{1.0 \times 10^{-14}}{1.0 \times 10^{-4}M} = 1.0 \times 10^{-10}M$$

$pH = -\log[H^+] = -\log(1.0 \times 10^{-10}M) = 10.00$

d. $$[H^+] = \frac{K_w}{[OH^-]} = \frac{1.0 \times 10^{-14}}{1.0 \times 10^{-9}M} = 1.0 \times 10^{-5}M$$

$pH = -\log[H^+] = -\log(1.0 \times 10^{-5}M) = 5.00$

103. **a.** +6 **b.** −2 **c.** +4 **d.** +2 **e.** 0 **f.** +4



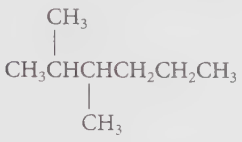
105. b; Ca is oxidized to Ca^{2+}, and Cl_2 is reduced to Cl^-.

c; Ca is oxidized to Ca^{2+}, and H^+ is reduced to H_2.

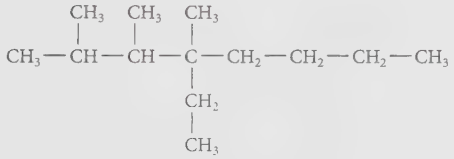
R112 Appendix E

Chapter 22

1.

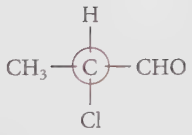


2. 10 single bonds



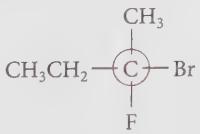
3. **a.** 3-ethylhexane **b.** 2-methylbutane

4. 4-ethyl-2-methylheptane



5.

6.



19. **a.**

b. no asymmetric carbon

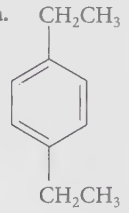
20. **a.**

b. no asymmetric carbon

42. pentane: $CH_3CH_2CH_2CH_2CH_3$
hexane: $CH_3CH_2CH_2CH_2CH_2CH_3$

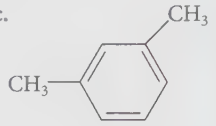
45. **a.** 2-methylbutane

b. 2,3-dimethylbutane



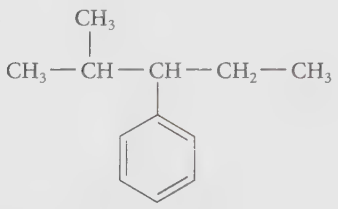
c. 3-methylhexane

47. **a.** unsaturated, because there is a double carbon-carbon bond



b. saturated, because the compound contains the maximum number of hydrogen atoms per carbon atom

52. No, only molecules with at least one asymmetric carbon can have enantiomers.



55. **a.**

c.

b.

58. The combustion of sulfur in coal produces the air pollutants SO_2 and SO_3.

60. **a.** Ethyne (acetylene) has one triple carbon-carbon bond and two single carbon-hydrogen bonds.

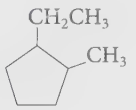
b. In methylbenzene, there are hybrid bonds within the ring. All other bonds are single bonds.

c. All the bonds in propane are single bonds.

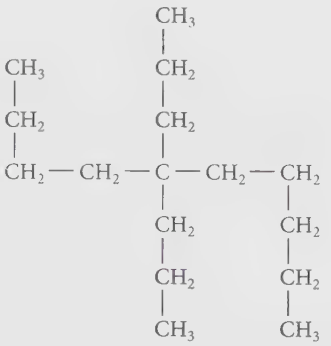
62. propane, butane, pentane

66. The middle structure is most stable due to resonance within the ring.

68. No, the structures are identical; one has been flipped over.



71. **a.** 4 **b.** 2 **c.** 3 **d.** 1



72. The amount of heat per carbon is higher for methane (−890 kJ/mol of carbon burned) than for benzene (−3268 ÷ 6 carbons = −545 kJ/mol of carbon burned). Burning aromatic compounds produces more soot.

76. $CH_2{=}C{=}CH_2$

Selected Solutions **R113**

78. a. $CH_3-CH_2-C(CH_3)=C(CH_3)-CH_2-CH_3$

b. 

c. 

82. a. $CH_3CH_2CH_2CH_2CH_3 \rightleftharpoons CH_3CH(CH_3)CH_2CH_3$

b. constitutional

c. 2-methylbutane

86. a. $C_6 = 5$, $C_7 = 9$, $C_8 = 18$, $C_9 = 35$, $C_{10} = 75$

b. As the size of the alkane molecule gets larger, the number of different ways that the carbon atoms can be bonded together (to form constitutional isomers) increases dramatically.

90. No, enantiomers have identical physical properties.

92. a. $6.20 \times 10^{-1}\ \cancel{\text{mol Cl}_2} \times \dfrac{22.4\ \text{L}}{1\ \cancel{\text{mol Cl}_2}} = 13.9\ \text{L}$

b. $V_2 = \dfrac{P_1 \times V_1}{P_2} = \dfrac{0.5\ \cancel{\text{kPa}} \times 6\ \text{L}}{3\ \cancel{\text{kPa}}} = 1\ \text{L}$

c. $P_X + P_Y + P_Z = P_{total}$

$P_X + 30\ \text{kPa} = 50\ \text{kPa}$

$P_X + 30\ \text{kPa} - 30\ \text{kPa} = 50\text{kPa} - 30\text{kPa}$

$P_X = 20\ \text{kPa}$

93. $750\ \cancel{\text{mL KNO}_3} \times \dfrac{1\ \text{L}\ \cancel{\text{KNO}_3}}{1000\ \cancel{\text{mL KNO}_3}} \times \dfrac{1.50\ \text{mol KNO}_3}{1\ \text{L}\ \cancel{\text{KNO}_3}}$

$= 1.13\ \text{mol KNO}_3$;

$1.13\ \cancel{\text{mol KNO}_3} \times \dfrac{101.1\ \text{g KNO}_3}{1.000\ \cancel{\text{mol KNO}_3}} = 114\ \text{g KNO}_3$

98. a. favors reactants b. favors products

100. a. $[H^+] = \dfrac{1.0 \times 10^{-14}}{[OH^-]} = \dfrac{1.0 \times 10^{-14}}{1.0 \times 10^{-4}} = 1.0 \times 10^{-10} M$

$pH = -\log[H^+] = -\log(1.0 \times 10^{-10}) = 10.00$

b. $[H^+] = \dfrac{1.0 \times 10^{-14}}{[OH^-]} = \dfrac{1.0 \times 10^{-14}}{3.9 \times 10^{-7}} = 2.6 \times 10^{-8} M$

$pH = -\log[H^+] = -\log(2.6 \times 10^{-8}) = 7.59$

c. $[H^+] = \dfrac{1.0 \times 10^{-14}}{[OH^-]} = \dfrac{1.0 \times 10^{-14}}{0.010} = 1.0 \times 10^{-12} M$

$pH = -\log[H^+] = -\log(1.0 \times 10^{-12}) = 12.00$

d. $[H^+] = \dfrac{1.0 \times 10^{-14}}{[OH^-]} = \dfrac{1.0 \times 10^{-14}}{5.0 \times 10^{-3}} = 2.0 \times 10^{-12} M$

$pH = -\log[H^+] = -\log(2.0 \times 10^{-12}) = 11.70$

102. a. H_3PO_4 c. H_2CO_3

b. CsOH d. $Be(OH)_2$

104. a. $2 + C + 3(-2) = 0$

$-4 + C = 0$

$C = +4$

Ca, +2; C, +4; O, −2

b. Cl, 0

c. $1 + I + 3(-2) = 0$

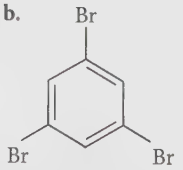
$I - 5 = 0$

$I = +5$

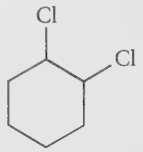
Li, +1; I, +5; O, −2

d. $2(+1) + S + 3(-2) = 0$

$S - 4 = 0$



$S = +4$



Na, +1; S, +4; O, −2

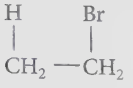
110. The reaction is nonspontaneous.

Chapter 23

33. a. $ClCH_2CCH_2CH_3$ (Cl on the second carbon)

b. 

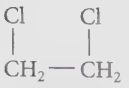
c. 



37. a. 2-propanol

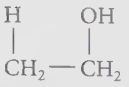
b. 1,2-propanediol

c. 2-methyl-2-propanol



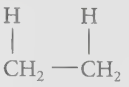
R114 Appendix E

38. **a.**



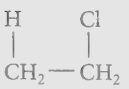
bromoethane

b.



1,2–dichloroethane

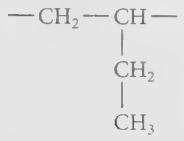
c.



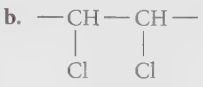
ethanol

d.

ethane



e.



chloroethane

42. **a.** propanone
b. ethanal
c. 3-methylbutanal
d. 3-hexanone
e. 2-phenylethanal
f. pentanoic acid

45. **a.**

b.

50. **a.** phenol
b. ether
c. alcohol
d. phenol
e. alcohol
f. ether

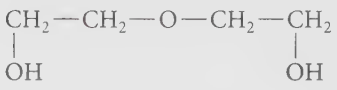
53. **a.** carboxyl group, ethanoic acid (acetic acid)
b. ether, diethyl ether (ethyl ether)
c. ketone (carbonyl group), propanone (acetone)
d. alcohol (hydroxy group), ethanol (ethyl alcohol)

57. The chemical properties (and toxicity) of organic compounds are determined by the compound as a whole. As a substituent in a molecule, a phenyl group ring does not have the same properties as benzene.

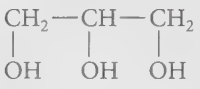
61. Ethanoic acid (two carbons long) is more soluble in water than decanoic acid (ten carbons long).

63. cadaverine, $H_2N(CH_2)_5NH_2$;
putrescine, $H_2N(CH_2)_4NH_2$
Both compounds are amines.

66.



69. Cholesterol is an alcohol with a hydroxy group on a cycloalkane. It has four nonaromatic rings. It has a double bond in one of its rings, as well as a large alkyl group, making the molecule nonpolar.



71. Waving lotion reduces —S—S— bonds to —SH bonds. Hair can be placed in curlers to form the hair in the desired shape. The neutralizing agent is an oxidizing agent that reforms —S—S— bonds, locking the hair into its curly shape. Similar steps could be used to straighten curly hair.

76. The two molecules are similar in size. Diethylene glycol has four carbons, and glycerol has three carbons. Diethylene glycol is an ether with two hydroxy groups. Glycerol has three hydroxy groups.

diethylene glycol

glycerol

78. b, 3

82. Anhydrous $Na_2CO_3(s)$ is the better value because the decahydrate is 63.0% water.

86. $\Delta T = 180°C - 22°C = 158°C$

$q = C_{Al} \times m \times \Delta T$

$$q = \frac{0.90 \cancel{J} \times \frac{1\ kJ}{10^3 \cancel{J}} \times 500 \cancel{g} \times 158 \cancel{°C}}{(\cancel{g} \cdot \cancel{°C})} = 71\ kJ$$

88. a, c, d, b

92. Reduction always occurs at the cathode. In an electrolytic cell, the cathode is the negative electrode.

94. coal

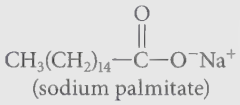
Chapter 24

42. Photosynthetic organisms use the sun's energy to synthesize carbon compounds, such as glucose, from CO_2 and H_2O.

47. Glucose is an aldehyde; fructose is a ketone.

53. Peptide chains fold into helixes or into pleated sheets in which peptide chains lie side by side.

64. phosphate group, sugar unit, nitrogen base



69. A substitution of one base for another may have no effect because the amino acid specified by the DNA code is not changed. Or a substitution of one base for another can result in a gene mutation in which the amino specified by the DNA code is changed.

70. Each individual's DNA is unique.

Selected Solutions **R115**

74. In catabolism, biological molecules are broken down and energy is released. In anabolism, energy and the products of catabolism are used to make biological molecules.

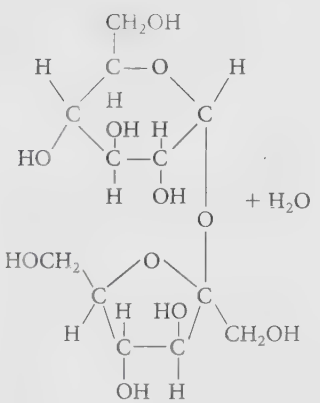
78.

(sodium palmitate)

82. C-G-x-C-C-x-T-C-A(or G)
Answers vary because there are multiple codes for the same amino acid.

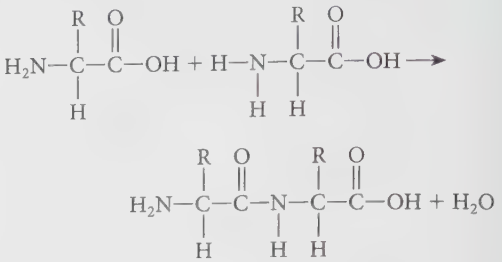
86. No; three code words specify the termination of a peptide chain.

88. Oxidation of each mol of glucose yields 38 mol ATP, so:



$$\frac{38\ \text{mol ATP} \times 30.5\ \text{kJ/mol ATP}}{2.82 \times 10^3\ \text{kJ}} \times 100\% = 41.1\%$$

89. $8400\ \text{kJ} \times \frac{1\ \text{mol ATP}}{30.5\ \text{kJ}} = 275\ \text{mol ATP}$



96. A monosaccharide (such as glucose and fructose) consists of a single simple sugar unit. A disaccharide (such as sucrose) consists of two linked monosaccharide units. A polysaccharide (such as starch or glycogen) consists of many linked monosaccharide units.

98. Base-pairing describes the hydrogen bonding that occurs between thymine (T) and adenine (A) and between cytosine (C) and guanine (G) in DNA. Base-pairing helps hold together the two DNA strands in a double helix.

104.

107. An amide group is formed by the reaction.

112. A-C-C-T-A-C-T-A-C
No; Leu has 6 possible code words.

119. **a.** Each formula unit of NaCl disassociates into 2 particles, so $0.507m \times 2 = 1.014m$.

$$\Delta T_b = K_b \times m = \frac{0.512°C}{\cancel{m}} \times 1.014\cancel{m} = 0.519°C$$

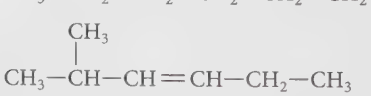
b. Each formula unit of NH_4Cl disassociates into 2 particles, so $0.204m \times 2 = 0.408m$.

$$\Delta T_b = K_b \times m = \frac{0.512°C}{\cancel{m}} \times 0.408\cancel{m} = 0.209°C$$

c. Each formula unit of $CaCl_2$ disassociates into 3 particles, so $0.155m \times 3 = 0.465m$.

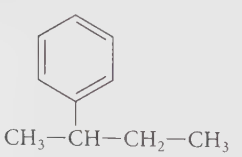
$$\Delta T_b = K_b \times m = \frac{0.512°C}{\cancel{m}} \times 0.465\cancel{m} = 0.238°C$$

d. Each formula unit of $NaHSO_4$ disassociates into 2 particles, so $0.222m \times 2 = 0.444m$.



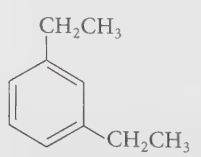
$$\Delta T_b = K_b \times m = \frac{0.512°C}{\cancel{m}} \times 0.444\cancel{m} = 0.227°C$$

120. $\Delta H = 0.265\ \cancel{\text{mol NaHCO}_3} \times \frac{129\ \text{kJ}}{2\ \cancel{\text{mol NaHCO}_3}}$



$= 17.1\ \text{kJ}$ heat absorbed

128. **a.** $CH_3-CH_2-CH_2-CH_2-CH_2-CH_2-CH_3$



b.

c.

d.

130. **a.** cyclopentane
b. 2-methyl-2-propanol
c. 3-pentanone

R116 Appendix E

Chapter 25

9. 10.4 h ÷ 2.6 h/half-life = 4 half-lives

$A = A_0\left(\frac{1}{2}\right)^4 = 1.0\text{ mg} \times \frac{1}{16} = 0.063\text{ mg Mn-56}$

10. 48.2 days ÷ 24.1 days/half-life = 2 half-lives

(Th-234 atoms) $\times \left(\frac{1}{2}\right)^2$ = (Th-234 atoms) $\times \frac{1}{4}$

No, $\frac{1}{4}$ of the Th-234 sample will remain.

36. $^{210}_{82}\text{Pb} \longrightarrow {}^{210}_{83}\text{Bi} + {}^{0}_{-1}\text{e}$

38. a. $^{238}_{92}\text{U} \longrightarrow {}^{234}_{90}\text{Th} + {}^{4}_{2}\text{He}$; thorium-234

b. $^{230}_{90}\text{Th} \longrightarrow {}^{226}_{88}\text{Ra} + {}^{4}_{2}\text{He}$; radium-226

c. $^{235}_{92}\text{U} \longrightarrow {}^{231}_{90}\text{Th} + {}^{4}_{2}\text{He}$; thorium-231

d. $^{222}_{86}\text{Rn} \longrightarrow {}^{218}_{84}\text{Po} + {}^{4}_{2}\text{He}$; polonium-218

40. a. mass number is unchanged; atomic number increases by 1

b. mass number decreases by 4; atomic number decreases by 2

c. Mass number and atomic number are both unchanged.

42. The atom undergoes radioactive decay.

47. n = 40 days ÷ 8 days/half-life = 5 half-lives

$A = A_0\left(\frac{1}{2}\right)^n = (20\text{ mg})\left(\frac{1}{2}\right)^5 = \frac{20}{32} = 0.625\text{ mg}$

0.625 mg of I-131 remains.

57. a. $^{30}_{15}\text{P} + {}^{0}_{-1}\text{e} \longrightarrow {}^{30}_{14}\text{Si}$

b. $^{13}_{6}\text{C} + {}^{1}_{0}\text{n} \longrightarrow {}^{14}_{6}\text{C}$

c. $^{131}_{53}\text{I} \longrightarrow {}^{131}_{54}\text{Xe} + {}^{0}_{-1}\text{e}$

65. $A = A_0\left(\frac{1}{2}\right)^n = (3.2 \times 10^7\text{ atoms})\left(\frac{1}{2}\right)^5$

$= \frac{3.2 \times 10^7\text{ atoms}}{32} = 1 \times 10^6\text{ atoms}$

67. a. $^{3}_{1}\text{H} \longrightarrow {}^{3}_{2}\text{H} + {}^{0}_{-1}\text{e}$

b. $^{28}_{12}\text{Mg} \longrightarrow {}^{28}_{13}\text{Al} + {}^{0}_{-1}\text{e}$

c. $^{131}_{53}\text{I} \longrightarrow {}^{131}_{54}\text{Xe} + {}^{0}_{-1}\text{e}$

d. $^{75}_{34}\text{Se} \longrightarrow {}^{75}_{35}\text{Br} + {}^{0}_{-1}\text{e}$

71. a. $^{0}_{-1}\text{e}$ b. $^{238}_{92}\text{U}$ c. $^{68}_{32}\text{Ge}$ d. $^{0}_{+1}\text{e}$

72. a. platinum d. titanium g. vanadium

b. thorium e. xenon h. palladium

c. francium f. californium

Thorium (b), francium (c), and californium (f) have no stable isotopes.

76. Carbon-14 has decayed $\frac{4\text{ counts/min}}{16\text{ counts/min}} = \frac{1}{4}$.

Since $\frac{1}{4} = \left(\frac{1}{2}\right)^2$, the artifact is 2 half-lives old.

One half-life is 5.73×10^3 years.

2 half-lives = $(5.73 \times 10^3) \times 2 = 11{,}460$ years.

82. $^{25}_{12}\text{Mg}$

84. $25\% = \frac{25}{100} = \frac{1}{4}$.

$\left(\frac{1}{2}\right)^n = \frac{1}{4}$, so n = 2 half-lives.

12.3 years × 2 half-lives = 24.6 years.

94. $\text{volume} = \frac{\text{mass}}{\text{density}} = \frac{8.0\text{ kg} \times \frac{1000\text{ g}}{1\text{ kg}}}{\frac{19\text{ g}}{1\text{ cm}^3}} = 4.2 \times 10^2\text{ cm}^3$

105. $10.00\text{ g Mg} \times \frac{1\text{ mol Mg}}{24.3\text{ g Mg}} \times \frac{1\text{ mol } H_2}{1\text{ mol Mg}} = 0.412\text{ mol } H_2$

$0.412\text{ mol } H_2 \times \frac{22.4\text{ L } H_2}{1\text{ mol } H_2} \times \frac{1000\text{ mL } H_2}{1\text{ L } H_2} \times \frac{1\text{ cm}^3\text{ } H_2}{1\text{ mL } H_2}$

$= 9.22 \times 10^3\text{ cm}^3\text{ } H_2$

107. $\text{volume} = \frac{\text{moles}}{\text{molarity}} = \frac{0.0020\text{ mol } Na_2SO_4}{\frac{0.30\text{ mol } Na_2SO_4}{1\text{ L}} \times \frac{1\text{ L}}{1000\text{ mL}}}$

$= 6.7\text{ mL}$

Selected Solutions **R117**

Glossary

A

absolute zero: the zero point on the Kelvin temperature scale, equivalent to −273.15°C *(79)*

cero absoluto: punto cero en la escala de temperatura Kelvin; equivale a −273.15°C

accepted value: a quantity used by general agreement of the scientific community *(65)*

valor aceptado: cantidad que se usa por acuerdo general de la comunidad científica

accuracy: the closeness of a measurement to the true value of what is being measured *(64)*

exactitud: qué tan cerca está una medición del valor real de lo que se mide

acid: a compound that produces hydrogen ions in solution; see also hydrogen-ion donor, Lewis acid *(285)*

ácido: compuesto que, en solución, produce iones hidrógeno; ver también donante iones hidrógeno, ácido de Lewis

acid dissociation constant (K_a): the ratio of the concentration of the dissociated form of an acid to the undissociated form; stronger acids have larger K_a values than weaker acids *(665)*

constante de disociación ácida (K_a): razón de la concentración de la forma disociada de un ácido a la concentración de la forma no disociada; los ácidos fuertes tienen valores K_a más altos que los ácidos débiles

acidic solution: any solution in which the hydrogen-ion concentration is greater than the hydroxide-ion concentration *(654)*

solución ácida: cualquier solución en la que la concentración de iones hidrógeno es mayor que la de iones hidróxido

activated complex: an unstable arrangement of atoms that exists momentarily at the peak of the activation-energy barrier; an intermediate or transitional structure formed during the course of a reaction *(596)*

complejo activado: acomodo inestable de átomos que existe momentáneamente en el punto más alto de la barrera de energía de activación; estructura intermedia o de transición que se forma en el curso de una reacción

activation energy: the minimum energy colliding particles must have in order to react *(596)*

energía de activación: energía mínima que deben tener las partículas para que, al chocar, reaccionen

active site: a groove or pocket in an enzyme molecule into which the substrate (reactant molecule) fits; where the substrate is converted to products *(847)*

sitio activo: hendidura o bolsa en una molécula de enzima, en la que embona el sustrato (molécula que reacciona); donde el sustrato se convierte en productos

activity series: a list of elements in order of decreasing activity; the activity series of halogens is Fl, Cl, Br, I *(360)*

serie de actividad: lista de elementos en orden de actividad decreciente; la serie de actividad de los halógenos es F, Cl, Br, I

actual yield: the amount of product that forms when a reaction is carried out in the laboratory *(405)*

rendimiento real: cantidad de producto que se forma cuando se lleva a cabo una reacción en el laboratorio

addition reaction: a reaction in which a substance is added at the double bond of an alkene or at the triple bond of an alkyne *(807)*

reacción de adición: reacción en la que una sustancia se añade al doble enlace de un alqueno o al triple enlace de un alquino

adenosine triphosphate (ATP): a molecule that transmits the energy needed by cells of all living things *(862)*

trifosfato de adenosina (ATP): molécula que transmite la energía que necesitan las células de todos los seres vivos

alcohol: an organic compound having an —OH (hydroxy) group; the general structure is R—OH *(804)*

alcohol: compuesto orgánico que posee un grupo —OH (hidroxilo); su estructura general es R—OH

aldehyde: an organic compound in which the carbon of the carbonyl group is joined to at least one hydrogen; the general formula is RCHO *(812)*

aldehído: compuesto orgánico en el que el carbono del grupo carbonilo está unido a por lo menos un hidrógeno; su fórmula general es RCHO

aliphatic hydrocarbon: any straight-chain or branched-chain alkane, alkene, or alkyne *(780)*

hidrocarburo alifático: cualquier alcano, alqueno o alquino de cadena lineal o cadena ramificada

alkali metal: any metal in Group 1A of the periodic table *(167)*

metal alcalino: cualquier metal del grupo 1A de la tabla periódica

alkaline earth metal: any metal in Group 2A of the periodic table *(167)*

metal alcalinotérreo: cualquier metal del grupo 2A de la tabla periódica

alkane: a hydrocarbon containing only single covalent bonds; alkanes are saturated hydrocarbons *(764)*

alcano: hidrocarburo que sólo contiene enlaces covalentes sencillos; los alcanos son hidrocarburos saturados

R118 Glossary

alkene: a hydrocarbon containing one or more carbon–carbon double bonds; alkenes are unsaturated hydrocarbons *(772)*
alqueno: hidrocarburo que contiene uno o más enlaces dobles carbono–carbono; los alquenos son hidrocarburos insaturados

alkyl group: a hydrocarbon substituent; the methyl group (—CH_3) is an alkyl group (768)
grupo alquilo: un hidrocarburo sustituto; el grupo metilo (—CH_3) es un grupo alquilo

alkyl halide: a halocarbon in which one or more halogen atoms are attached to the carbon atoms of an aliphatic chain *(800)*
haluro de alquilo: compuesto halocarbonado en el que uno o más átomos de halógeno están unidos a los átomos de carbono de una cadena alifática

alkyne: a hydrocarbon containing a carbon–carbon triple bond; alkynes are unsaturated hydrocarbons *(773)*
alquino: hidrocarburo que contiene un triple enlace carbono–carbono; los alquinos son hidrocarburos insaturados

allotrope: one of two or more different molecular forms of an element in the same physical state; oxygen (O_2) and ozone (O_3) are allotropes of the element oxygen *(434)*
alótropo: una de dos o más formas moleculares distintas de un elemento en el mismo estado físico; el oxígeno (O_2) y el ozono (O_3) son alótropos del elemento oxígeno

alloy: a mixture composed of two or more elements, at least one of which is a metal *(211)*
aleación: mezcla formada por dos o más elementos, donde al menos uno de ellos es un metal

alpha particle: a positively charged particle emitted from certain radioactive nuclei; it consists of two protons and two neutrons and is identical to the nucleus of a helium atom *(877)*
partícula alfa: partícula con carga positiva emitida por ciertos núcleos radiactivos; consta de dos protones y dos neutrones, y es idéntica al núcleo de un átomo de helio

amine: an organic compound in which nitrogen is bonded to a carbon group *(811)*
amina: compuesto orgánico en el cual el nitrógeno se enlaza a un grupo de carbonos

amino acid: an organic compound having amino (—NH_2) and carboxyl (—COOH) groups in the same molecule; proteins are made from the 20 naturally occurring amino acids *(844)*
aminoácido: compuesto orgánico que posee grupos amino (—NH_2) y carboxilo (—COOH) en la misma molécula; las proteínas se forman a partir de los 20 aminoácidos naturales

amorphous solid: describes a solid that lacks an ordered internal structure; denotes a random arrangement of atoms *(434)*
sólido amorfo: describe un sólido que carece de una estructura interna ordenada; denota un acomodo aleatorio de átomos

amphoteric: a substance that can act as both an acid and a base *(651)*
anfótero: una sustancia que puede actuar como ácido y también como base

amplitude: the height of a wave's crest *(138)*
amplitud: altura de la cresta de una onda

anabolism: synthesis processes in the metabolism of cells; these processes usually require the expenditure of energy *(864)*
anabolismo: procesos de síntesis dentro del metabolismo de las células; por lo regular, esos procesos requieren gasto de energía

analytical chemistry: the area of chemistry that focuses on the composition of matter *(3)*
química analítica: rama de la química que estudia la composición de la materia

anhydrous: describes a substance that does not contain water *(498)*
anhidro: se refiere a una sustancia que no contiene agua

anion: any atom or group of atoms with a negative charge *(176)*
anión: cualquier átomo o grupo de átomos que posee carga negativa

anode: the electrode at which oxidation occurs *(730)*
ánodo: electrodo en el que hay oxidación

applied chemistry: research that is directed toward a practical goal or application *(3)*
química aplicada: investigaciones que tienen una meta o aplicación práctica

aqueous solution: water that contains dissolved substances *(494)*
solución acuosa: agua que contiene sustancias disueltas

aromatic compound: an organic compound that contains a benzene ring or other ring in which the bonding is like that of benzene; aromatic compounds are also known as arenes *(780)*
compuesto aromático: compuesto orgánico que contiene un anillo bencénico u otro anillo con enlaces similares a los del benceno; los compuestos aromáticos también se conocen como arenos

aryl halide: a halocarbon in which one or more halogens are attached to the carbon atoms of an arene ring *(800)*
haluro de arilo: compuesto en el que uno o más átomos de halógeno están unidos a átomos de carbono de un anillo de areno

Glossary **R119**

asymmetric carbon: a carbon atom that has four different atoms or groups attached *(776)*
carbono asimétrico: átomo de carbono unido a cuatro átomos o grupos distintos

atmospheric pressure: the pressure exerted by atoms and molecules in the atmosphere surrounding Earth, resulting from collisions of these particles with objects *(421)*
presión atmosférica: presión ejercida por átomos y moléculas de la atmósfera que rodea a la Tierra y que resulta de los choques de dichas partículas con los objetos

atom: the smallest particle of an element that retains its identity in a chemical reaction *(102)*
átomo: partícula más pequeña de un elemento que conserva su identidad en una reacción química

atomic emission spectrum: the pattern formed when light passes through a prism or diffraction grating to separate it into the different frequencies of light it contains *(140)*
espectro de emisión atómica: patrón que se forma cuando la luz atraviesa un prisma o una rejilla de difracción que la separa en las dife-rentes frecuencias de luz que contiene

atomic mass: the weighted average of the masses of the isotopes of an element *(117)*
masa atómica: promedio ponderado de las masas de los isótopos de un elemento

atomic mass unit (amu): a unit of mass equal to one-twelfth the mass of a carbon-12 atom *(116)*
unidad de masa atómica (uma): unidad de masa igual a un doceavo de la masa de un átomo de carbono 12

atomic number: the number of protons in the nucleus of an atom of an element *(112)*
número atómico: número de protones que hay en el núcleo del átomo de un elemento

atomic orbital: a mathematical expression describing the probability of finding an electron at various locations; usually represented by the region of space around the nucleus where there is a high probability of finding an electron *(131)*
orbital atómico: expresión matemática que describe la probabilidad de hallar un electrón en diversos lugares; se suele representar como la región del espacio en torno al núcleo donde hay una probabilidad elevada de hallar un electrón

atomic radius: one-half the distance between the nuclei of two atoms of the same element when the atoms are joined *(174)*
radio atómico: mitad de la distancia entre los núcleos de dos átomos del mismo elemento cuando dichos átomos están unidos

aufbau principle: the rule that electrons occupy the orbitals of lowest energy first *(134)*
principio de aufbau: regla según la cual los electrones primero ocupan los orbitales de energía más baja

Avogadro's hypothesis: equal volumes of gases at the same temperature and pressure contain equal numbers of particles *(320)*
hipótesis de Avogadro: volúmenes iguales de gases a la misma temperatura y presión contienen el mismo número de partículas

Avogadro's number: the number of representative particles contained in one mole of a substance; equal to 6.02×10^{23} particles *(308)*
número de Avogadro: número de partículas representativas contenidas en un mol de una sustancia; es igual a 6.02×10^{23} partículas

B

balanced equation: a chemical equation in which mass is conserved; each side of the equation has the same number of atoms of each element *(350)*
ecuación balanceada: ecuación química en la que se conserva la masa; cada lado de la ecuación tiene el mismo número de átomos de cada elemento

band of stability: the location of stable nuclei on a neutron-vs.-proton plot *(880)*
banda de estabilidad: región ocupada por los núcleos estables en un diagrama neutrones-protones

barometer: an instrument used to measure atmospheric pressure *(421)*
barómetro: instrumento que sirve para medir la presión atmosférica

base: a compound that produces hydroxide ions in solution; see also hydrogen-ion acceptor, Lewis base *(287)*
base: compuesto que, en solución, produce iones hidróxido, ver también receptor de iones hidrógeno, base de Lewis

base dissociation constant (K_b): the ratio of the concentration of the conjugate acid times the concentration of the hydroxide ion to the concentration of the base *(668)*
constante de disociación básica (K_b): razón de la concentración del ácido combinado multiplicada por la concentración del ion hidróxido, a la concentración de la base

basic solution: any solution in which the hydroxide-ion concentration is greater than the hydrogen-ion concentration *(654)*
solución básica: cualquier solución en la que la concentración de ion hidróxido es mayor que la concentración de ion hidrógeno

battery: a group of voltaic cells that are connected to one another *(733)*
batería: grupo de celdas voltaicas conectadas entre sí

beta particle: an electron resulting from the breaking apart of neutrons in an atom *(878)*
partícula beta: electrón que se produce al descomponerse los neutrones de un átomo

R120 Glossary

binary compound: a compound composed of two elements; NaCl and Al_2O_3 are binary compounds *(272)*
compuesto binario: compuesto integrado por dos elementos; NaCl y Al_2O_3 son compuestos binarios

biochemistry: the area of chemistry that focuses on processes that take place in organisms *(3)*
bioquímica: rama de la química que se concentra en los procesos que se dan en los organismos

boiling point (bp): the temperature at which the vapor pressure of a liquid is just equal to the external pressure on the liquid *(428)*
punto de ebullición (p. eb.): temperatura en la que la presión de vapor de un líquido es apenas igual a la presión externa sobre el líquido

boiling-point elevation: the difference in temperature between the boiling point of a solution and the boiling point of the pure solvent *(537)*
incremento del punto de ebullición: diferencia de temperatura entre el punto de ebullición de una solución y el punto de ebullición del disolvente puro

bond dissociation energy: the energy required to break the bond between two covalently bonded atoms; this value is usually expressed in kJ per mol of substance *(236)*
energía de disociación de enlaces: energía requerida para romper el enlace entre dos átomos unidos de forma covalente; este valor suele expresarse en kJ por mol de sustancia

bonding orbital: a molecular orbital that can be occupied by two electrons of a covalent bond *(240)*
orbital de enlace: orbital molecular que puede ser ocupado por los dos electrones de un enlace covalente

Boyle's law: for a given mass of gas at constant temperature, the volume of the gas varies inversely with pressure *(456)*
ley de Boyle: para una masa dada de gas a temperatura constante, el volumen del gas varía en proporción inversa con la presión

branched-chain alkane: an alkane with one or more alkyl groups attached to the parent structure *(768)*
alcano de cadena ramificada: alcano con uno o más grupos alquilo unidos a la estructura madre

Brownian motion: the chaotic movement of colloidal particles, caused by collision with particles of the solvent in which they are dispersed *(506)*
movimiento browniano: movimiento caótico de partículas coloidales, debido a los choques con las partículas del disolvente en el que están dispersas

buffer: a solution in which the pH remains relatively constant when small amounts of acid or base are added; a buffer can be either a solution of a weak acid and the salt of a weak acid or a solution of a weak base with the salt of a weak base *(678)*
solución amortiguadora: solución cuyo pH permanece relativamente constante si se le añaden pequeñas cantidades de ácido o base; una solución amortiguadora puede ser una solución de un ácido débil y la sal de un ácido débil o una solución de una base débil y la sal de una base débil

buffer capacity: a measure of the amount of acid or base that may be added to a buffer solution before a significant change in pH occurs *(679)*
capacidad amortiguadora: medida de la cantidad de ácido o base que se puede añadir a una solución amortiguadora sin que haya un cambio importante del pH

C

calorie (cal): the quantity of heat needed to raise the temperature of 1 g of pure water 1°C *(77)*
caloría (cal): cantidad de calor necesaria para elevar 1°C la temperatura de 1 g de agua pura

calorimeter: an insulated device used to measure the absorption or release of heat in chemical or physical processes *(562)*
calorímetro: aparato con material aislante que sirve para medir la absorción o desprendimiento de calor durante procesos químicos o físicos

calorimetry: the precise measurement of heat flow out of a system for chemical and physical processes *(562)*
calorimetría: medición precisa del cambio del calor durante procesos químicos y físicos

carbohydrate: the name given to monomers and polymers of aldehydes and ketones that have numerous hydroxyl groups; sugars and starches are carbohydrates *(841)*
carbohidrato: nombre dado a monómeros y polímeros de aldehídos y cetonas que tienen muchos grupos hidroxilo; los azúcares y almidones son carbohidratos

carbonyl group: a functional group having a carbon atom and an oxygen atom joined by a double bond; it is found in aldehydes, ketones, esters, and amides *(812)*
grupo carbonilo: grupo funcional que consiste en un átomo de carbono y uno de oxígeno unidos por un doble enlace; se le encuentra en aldehídos, cetonas, ésteres y amidas

carboxyl group: a functional group consisting of a carbonyl group attached to a hydroxyl group; it is found in carboxylic acids *(815)*
grupo carboxilo: grupo funcional que consiste en un grupo carbonilo unido a un grupo hidroxilo; se le encuentra en los ácidos carboxílicos

Glossary **R121**

carboxylic acid: an organic acid containing a carboxyl group; the general formula is RCOOH *(815)*
ácido carboxílico: ácido orgánico que contiene un grupo carboxilo; su fórmula general es RCOOH

catabolism: the reactions in living cells in which substances are broken down and energy is produced *(863)*
catabolismo: reacción, dentro de las células vivas, por la que diversas sustancias se descomponen y producen energía

catalyst: a substance that increases the rate of reaction by lowering the activation-energy barrier; the catalyst is not used up in the reaction *(348)*
catalizador: sustancia que aumenta la velocidad de reacción disminuyendo la barrera de energía de activación; el catalizador no se consume en la reacción

cathode: the electrode at which reduction occurs *(730)*
cátodo: electrodo en el que hay reducción

cathode ray: a stream of electrons produced at the negative electrode (cathode) of a tube containing a gas at low pressure *(105)*
rayo catódico: haz de electrones producido en el electrodo negativo (cátodo) de un tubo que contiene un gas a baja presión

cation: any atom or group of atoms with a positive charge *(176)*
catión: cualquier átomo o grupo de átomos que posee carga positiva

cell potential: the difference between the reduction potentials of two half-cells *(737)*
potencial de celda: diferencia entre los potenciales de reducción de dos medias celdas

Celsius scale: the temperature scale on which the freezing point of water is 0°C and the boiling point is 100°C *(78)*
escala Celsius: escala de temperatura en la que el punto de congelación del agua es 0°C y el punto de ebullición del agua es 100°C

Charles's law: the volume of a fixed mass of gas is directly proportional to its Kelvin temperature if the pressure is kept constant *(458)*
ley de Charles: el volumen de una masa fija de gas es directamente proporcional a su temperatura Kelvin si la presión se mantiene constante

chemical change: a change that produces matter with a different composition than the original matter *(43)*
cambio químico: cambio que produce materia con una composición diferente que la de la materia original

chemical equation: an expression representing a chemical reaction; the formulas of the reactants (on the left) are connected by an arrow with the formulas for the products (on the right) *(348)*
ecuación química: expresión que representa una reacción química; las fórmulas de los reactantes (a la izquierda) se unen mediante una flecha a las fórmulas de los productos (a la derecha)

chemical equilibrium: a state of balance in which the rates of the forward and reverse reactions are equal; no net change in the amount of reactants and products occurs in the chemical system *(610)*
equilibrio químico: estado de equilibrio en el que las velocidades de la reacción de evolución y la reacción inversa son iguales; no hay un cambio total en la cantidad de reactantes y productos en el sistema químico

chemical formula: an expression that indicates the number and type of atoms present in the smallest representative unit of a substance *(202)*
fórmula química: expresión que indica el número y tipo de átomos que están presentes en la unidad más pequeña representativa de una sustancia

chemical potential energy: energy stored in chemical bonds *(556)*
energía potencial química: energía almacenada en los enlaces químicos

chemical property: the ability of a substance to undergo a specific chemical change *(48)*
propiedad química: capacidad de una sustancia para sufrir un cambio químico específico

chemical reaction: a change in which one or more reactants change into one or more products; characterized by the breaking of bonds in reactants and the formation of bonds in products *(48)*
reacción química: cambio en el que uno o más reactantes se convierten en uno o más productos; se caracteriza por la ruptura de enlaces en los reactantes y la formación de enlaces en los productos

chemical symbol: a one- or two-letter representation of an element *(45)*
símbolo químico: representación de un elemento que emplea una o dos letras

chemistry: the study of the composition of matter and the changes that matter undergoes *(2)*
química: estudio de la composición de la materia y los cambios que ésta sufre

***cis* configuration:** the configuration in which substituent groups are on the same side of a double bond *(776)*
configuración *cis*: configuración en la cual los grupos sustitutos están del mismo lado de un doble enlace

***cis-trans* isomers:** compounds that have atoms in the same order, but differ in the orientation of groups around a double bond *(776)*
isómeros *cis-trans*: compuestos cuyos átomos tienen el mismo orden, pero difieren con respecto a la orientación de los grupos alrededor de un enlace doble

coefficient: a small whole number that appears in front of a formula in a balanced chemical equation *(350)*
coeficiente: número entero pequeño que aparece antepuesto a una fórmula en una ecuación química balanceada

R122 Glossary

coenzyme: a small organic molecule or metal ion necessary for an enzyme's biological activity *(848)*
coenzima: pequeña molécula orgánica o ion metálico que se requiere para que una enzima tenga actividad biológica

colligative property: a property of a solution that depends only upon the number of solute particles, and not upon their identities; boiling-point elevation, freezing-point depression, and vapor-pressure lowering are colligative properties *(534)*
propiedad coligativa: propiedad de una solución que depende únicamente del número de partículas de soluto, y no del tipo de soluto; el incremento del punto de ebullición, la disminución del punto de congelación y el descenso de la presión de vapor son propiedades coligativas

collision theory: atoms, ions, and molecules can react to form products when they collide, provided that the particles have enough kinetic energy *(596)*
teoría de choques: los átomos, iones y moléculas pueden reaccionar para formar productos cuando chocan, siempre que las partículas tengan suficiente energía cinética

colloid: a mixture whose particles are intermediate in size between those of a suspension and a solution *(505)*
coloide: mezcla cuyas partículas tienen un tamaño intermedio entre las de una suspensión y una solución

combination reaction: a chemical change in which two or more substances react to form a single new substance; also called a synthesis reaction *(356)*
reacción de combinación: cambio químico en el que dos o más sustancias reaccionan para formar una sola sustancia nueva; también llamado reacción de síntesis

combined gas law: the law that describes the relationship among the pressure, temperature, and volume of an enclosed gas *(462)*
ley combinada de los gases: ley que describe las relaciones entre la presión, la temperatura y el volumen de un gas encerrado

combustion reaction: a chemical change in which an element or a compound reacts with oxygen, often producing energy in the form of heat and light *(363)*
reacción de combustión: cambio químico en el que un elemento o un compuesto reacciona con oxígeno y por lo regular produce energía en forma de luz y calor

common ion: an ion that is common to both salts in a solution; in a solution of silver nitrate and silver chloride, Ag^+ would be a common ion *(624)*
ion común: ion que es común a dos sales disueltas en una solución; en una solución de nitrato de plata y cloruro de plata, Ag^+ sería un ion común

common ion effect: a decrease in the solubility of an ionic compound caused by the addition of a common ion *(624)*
efecto de ion común: disminución en la solubilidad de un compuesto iónico debida a la adición de un ion común

complete ionic equation: an equation that shows dissolved ionic compounds as dissociated free ions *(370)*
ecuación iónica completa: ecuación que muestra los compuestos iónicos disueltos en forma de iones disociados libres

compound: a substance that contains two or more elements chemically combined in a fixed proportion *(42)*
compuesto: sustancia que contiene dos o más elementos combinados químicamente en una proporción fija

compressibility: a measure of how much the volume of matter decreases under pressure *(450)*
compresibilidad: medida de cuánto disminuye el volumen de la materia cuando se le aplica presión

concentrated solution: a solution containing a large amount of solute *(525)*
solución concentrada: solución que contiene una gran cantidad de soluto

concentration: a measurement of the amount of solute that is dissolved in a given quantity of solvent; usually expressed as mol/L *(525)*
concentración: medida de la cantidad de soluto que está disuelto en una cantidad específica de disolvente; suele expresarse en mol/L

condensed structural formula: a structural formula that leaves out some bonds and/or atoms; the presence of these atoms or bonds is understood *(766)*
fórmula estructural condensada: fórmula estructural que no muestra algunos enlaces o átomos; se sobreentiende la presencia de estos enlaces o átomos

conjugate acid: the particle formed when a base gains a hydrogen ion; NH_4^+ is the conjugate acid of the base NH_3 *(650)*
ácido conjugado: partícula que se forma cuando una base gana un ion hidrógeno; NH_4^+ es el ácido conjugado de la base NH_3

conjugate acid-base pair: two substances that are related by the loss or gain of a single hydrogen ion; ammonia (NH_3) and the ammonium ion (NH_4^+) are a conjugate acid-base pair *(650)*
par conjugado ácido-base: dos sustancias relacionadas entre sí por la pérdida o ganancia de un solo ion hidrógeno; el amoníaco (NH_3) y el ion amonio (NH_4^+) son un par conjugado ácido-base

conjugate base: the particle that remains when an acid has donated a hydrogen ion; OH^- is the conjugate base of the acid water *(650)*
base conjugada: partícula que queda cuando un ácido transfiere un ion hidrógeno; OH^- es la base conjugada del ácido agua

constitutional isomers: compounds that have the same molecular formula, but whose atoms are bonded in a different order *(775)*
isómeros constitucionales: compuestos que tienen la misma fórmula molecular, pero cuyos átomos están enlazados en distinto orden

Glossary **R123**

conversion factor: a ratio of equivalent measurements used to convert a quantity from one unit to another *(84)*
factor de conversión: razón de medidas equivalentes usadas para convertir una cantidad de una unidad a otra

coordinate covalent bond: a covalent bond in which one atom contributes both bonding electrons *(232)*
enlace covalente coordinado: enlace covalente en el que un átomo aporta dos electrones de enlace

coordination number: the number of ions of opposite charge that surround each ion in a crystal *(205)*
número de coordinación: número de iones de carga opuesta que rodean a cada ion en un cristal

covalent bond: a bond formed by the sharing of electrons between atoms *(215)*
enlace covalente: enlace que se forma cuando dos átomos comparten electrones

cracking: the controlled process by which hydrocarbons are broken down or rearranged into smaller, more useful molecules *(783)*
pirólisis: proceso controlado por el cual los hidrocarburos se descomponen o reacomodan para obtener moléculas más pequeñas y útiles

crystal: a solid in which the atoms, ions, or molecules are arranged in an orderly, repeating, three-dimensional pattern called a crystal lattice *(432)*
cristal: sólido en el que los átomos, iones o moléculas están dispuestos en un patrón tridimensional ordenado y repetitivo llamado red cristalina

cycloalkane: cyclic hydrocarbon that contains only single bonds *(779)*
cicloalcano: hidrocarburo cíclico que solamente contiene enlaces simples

cyclic hydrocarbon: an organic compound that contains a hydrocarbon ring *(779)*
hidrocarburo cíclico: compuesto orgánico que contiene un anillo de hidrocarburo

D

Dalton's atomic theory the first theory to relate chemical changes to events at the atomic level *(103)*
teoría atómica de Dalton: primera teoría en relacionar los cambios químicos con sucesos a nivel atómico

Dalton's law of partial pressures: at constant volume and temperature, the total pressure exerted by a mixture of gases is equal to the sum of the partial pressures of the component gases *(470)*
teoría de Dalton de las presiones parciales: a volumen y temperatura constantes, la presión total ejercida por una mezcla de gases es igual a la suma de las presiones parciales de los gases componentes

decomposition reaction: a chemical change in which a single compound is broken down into two or more simpler products *(358)*
reacción de descomposición: cambio químico en el que un solo compuesto se descompone en dos o más productos más simples

dehydrogenation reaction: a reaction in which hydrogen is lost *(816)*
reacción de deshidrogenación: reacción en la que se pierde hidrógeno

deliquescent: describes a substance that removes sufficient water from the air to form a solution; the solution formed has a lower vapor pressure than that of the water in the air *(501)*
delicuescente: término que describe una sustancia que absorbe suficiente humedad del aire como para formar una solución; la solución formada tiene una presión de vapor más baja que la de la humedad del aire

density: the ratio of the mass of an object to its volume *(80)*
densidad: razón de la masa de un objeto a su volumen

dependent variable: the variable that is observed during an experiment; also called responding variable *(16)*
variable dependiente: variable que se observa durante un experimento; también llamada variable de repuesta

desiccant: a hygroscopic substance used as a drying agent *(499)*
desecante: sustancia higroscópica empleada como agente secante

diatomic molecule: a molecule consisting of two atoms *(223)*
molécula diatómica: molécula que cons-ta de dos átomos

diffusion: the tendency of molecules to move toward areas of lower concentration until the concentration is uniform throughout *(472)*
difusión: tendencia de las moléculas a moverse hacia áreas de baja concentración hasta que la concentración es uniforme en todo el medio

dilute solution: a solution that contains a small amount of solute *(525)*
solución diluida: solución que contiene muy poco soluto

dimensional analysis: a technique of problem-solving that uses the units that are part of a measurement to help solve the problem *(86)*
análisis dimensional: técnica para resolver problemas que se apoya en las unidades de las mediciones para resolver el problema

dipole: a molecule that has two poles, or regions, with opposite charges *(249)*
dipolo: molécula que tiene dos polos o regiones de carga opuesta

R124 Glossary

dipole interactions: intermolecular forces resulting from the attraction of oppositely charged regions of polar molecules *(250)*

interacción dipolar: fuerzas intermoleculares que resultan de la atracción de regiones de moléculas polares que tienen cargas opuestas

diprotic acid: any acid that contains two ionizable protons (hydrogen ions); sulfuric acid (H_2SO_4) is a diprotic acid *(647)*

ácido diprótico: cualquier ácido que contenga dos protones (iones hidrógeno) ionizables; el ácido sulfúrico (H_2SO_4) es un ácido diprótico

disaccharide: a carbohydrate formed from two monosaccharide units; common table sugar (sucrose) is a disaccharide *(842)*

disacárido: carbohidrato formado por dos unidades de monosacárido; el azúcar de mesa común (sacarosa) es un disacárido

dispersion forces: attractions between molecules caused by the electron motion on one molecule affecting the electron motion on the other through electrical forces; these are the weakest interactions between molecules *(251)*

fuerzas de dispersión: atracciones entre moléculas que se dan cuando el movimiento de los electrones de una molécula afecta el movimiento de los electrones de la otra mediante fuerzas eléctricas; se trata de las interacciones más débiles entre moléculas

displacement reaction: see single-replacement reaction

reacción de desplazamiento: véase reacción de sustitución sencilla

distillation: a process used to separate components of a mixture using differences in boiling points *(40)*

destilación: proceso que se emplea para separar las sustancias de una mezcla por medio de diferentes puntos de ebullición

double covalent bond: a bond in which two atoms share two pairs of electrons *(230)*

enlace covalente doble: enlace en el que dos átomos comparten dos pares de electrones

double-replacement reaction: a chemical change that involves an exchange of positive ions between two compounds *(362)*

reacción de sustitución doble: cambio químico que implica un intercambio de iones positivos entre dos compuestos

dry cell: a commercial voltaic cell in which the electrolyte is a moist paste; despite their name, the compact, portable batteries used in flashlights are dry cells *(732)*

pila seca: celda voltaica comercial en la que, a pesar del nombre, el electrolito es una pasta húmeda; las baterías compactas y portátiles que se usan en las linternas son pilas secas

E

effloresce: to lose water of hydration; the process occurs when the hydrate has a vapor pressure higher than that of water vapor in the air *(499)*

eflorecerse: perder agua de hidratación; el proceso se presenta cuando la presión de vapor del hidrato es más alta que la del vapor de agua en el aire

effusion: the process that occurs when a gas escapes through a tiny hole in its container *(472)*

efusión: proceso en el cual un gas escapa por un agujero diminuto en su recipiente

electrical potential: the ability of a voltaic cell to produce an electric current *(737)*

potencial eléctrico: capacidad de una celda voltaica para producir corriente eléctrica

electrochemical cell: any device that converts chemical energy into electrical energy or electrical energy into chemical energy *(730)*

celda electroquímica: cualquier dispositivo que convierte energía química en energía eléctrica o energía eléctrica en energía química

electrochemical process: the conversion of chemical energy into electrical energy or electrical energy into chemical energy; all electrochemical processes involve redox reactions *(728)*

proceso electroquímico: conversión de energía química en energía eléctrica o energía eléctrica en energía química; en todos los procesos electroquímicos intervienen reacciones redox

electrode: a conductor in a circuit that carries electrons to or from a substance other than a metal *(730)*

electrodo: en un circuito, un conductor que transporta electrones hacia o desde una sustancia que no es un metal

electrolysis: a process in which electrical energy is used to bring about a chemical change; the electrolysis of water produces hydrogen and oxygen *(745)*

electrolisis: proceso en el que se usa energía eléctrica para realizar un cambio químico; la electrolisis del agua produce hidrógeno y oxígeno

electrolyte: a compound that conducts an electric current when it is in an aqueous solution or in the molten state; all ionic compounds are electrolytes, but most covalent compounds are not *(496)*

electrolito: compuesto que conduce una corriente eléctrica cuando está en solución acuosa o está derretido; todos los compuestos iónicos son electrolitos, pero muy pocos compuestos covalentes lo son

electrolytic cell: an electrochemical cell used to cause a chemical change through the application of electrical energy *(745)*

celda electrolítica: celda electroquímica que se usa para efectuar un cambio químico mediante la aplicación de energía eléctrica

Glossary **R125**

electromagnetic radiation: energy waves that travel in a vacuum at a speed of 2.998×10^8 m/s; includes radio waves, microwaves, infrared waves, visible light, ultraviolet waves, X-rays, and gamma rays *(139)*

radiación electromagnética: ondas de energía que viajan en el vacío a una velocidad de 2.998×10^8 m/s; incluye las ondas de radio, microondas, ondas infrarrojas, luz visible, ondas ultravioleta, rayos X y rayos gamma

electron: a negatively charged subatomic particle *(105)*

electrón: partícula subátomica con carga negativa

electron configuration: the arrangement of electrons of an atom in its ground state into various orbitals around the nuclei of atoms *(134)*

configuración electrónica: distribución de los electrones de un átomo en su estado basal, en diversos orbitales alrededor del núcleo del átomo

electron dot structure: a notation that depicts valence electrons as dots around the atomic symbol of the element; the symbol represents the inner electrons and atomic nucleus; also called Lewis dot structure *(195)*

estructura de punto electrón: notación que muestra los electrones de valencia como puntos alrededor del símbolo atómico del elemento; el símbolo representa los electrones internos y el núcleo atómico; también se conoce como estructura de puntos de Lewis

electronegativity: the ability of an atom to attract electrons when the atom is in a compound *(181)*

electronegatividad: capacidad de un átomo para atraer electrones cuando el átomo está en un compuesto

element: the simplest form of matter that has a unique set of properties; an element cannot be broken down into simpler substances by chemical means *(42)*

elemento: forma más simple de materia que posee un conjunto único de propiedades; un elemento no puede descomponerse en sustancias más simples usando métodos químicos

elementary reaction: a reaction in which reactants are converted to products in a single step *(607)*

reacción básica: reacción en la que los reactantes se convierten en productos en un solo paso

empirical formula: a formula with the lowest whole-number ratio of elements in a compound; the empirical formula of hydrogen peroxide (H_2O_2) is HO *(330)*

fórmula empírica: fórmula que muestra las proporciones de los elementos en un compuesto con los números enteros más pequeños posibles; la fórmula empírica del peróxido de hidrógeno (H_2O_2) es HO

emulsion: the colloidal dispersion of one liquid in another *(507)*

emulsión: dispersión coloidal de un líquido en otro

enantiomers: molecules that differ from one another in the way that four different groups are arranged around a carbon atom *(777)*

enantiómero: moléculas que se diferencian entre sí por la forma en que cuatro grupos diferentes están dispuestos alrededor de un átomo de carbono

endothermic process: a process that absorbs heat from the surroundings *(557)*

proceso endotérmico: proceso en el que se absorbe calor del entorno

end point: the point in a titration at which the indicator changes color *(674)*

punto final: punto de una valoración química en cual el indicador cambia de color

energy: the capacity for doing work or producing heat *(77)*

energía: capacidad para efectuar trabajo o producir calor

energy level: the specific energies an electron in an atom or other system can have *(129)*

nivel energético: las energías específicas que puede tener un electrón en un átomo u otro sistema

enthalpy (H): the heat content of a system at constant pressure *(562)*

entalpía (H): cantidad de calor en un sistema a presión constante

entropy (S): a measure of the disorder of a system; systems tend to go from a state of order (low entropy) to a state of maximum disorder (high entropy) *(630)*

entropía (S): medida del desorden de un sistema; los sistemas tienden a pasar de un estado ordenado (baja entropía) a un estado de máximo desorden (alta entropía)

enzyme: a protein that acts as a biological catalyst *(847)*

enzima: proteína que actúa como catalizador biológico

enzyme–substrate complex: the structure formed when a substrate molecule joins an enzyme at its active site *(847)*

complejo enzima-sustrato: estructura que se forma cuando una molécula de sustrato se une a una enzima en su sitio activo

equilibrium constant (K_{eq}): the ratio of product concentrations to reactant concentrations at equilibrium, with each concentration raised to a power equal to the number of moles of that substance in the balanced chemical equation *(616)*

constante de equilibrio (K_{eq}): razón de las concentraciones de los productos a las concentraciones de los reactantes en el equilibrio, con cada concentración elevada a una potencia igual al número de moles de esa sustancia en la ecuación química balanceada

equilibrium position: the relative concentrations of reactants and products of a reaction that has reached equilibrium; indicates whether the reactants or products are favored in the reversible reaction *(611)*

posición de equilibrio: las concentraciones relativas de reactantes y productos de una reacción que ha alcanzado el equilibrio; indica si se favorecen los reactantes o productos en la reacción reversible

R126 Glossary

equivalence point: the point in a titration where the number of moles of hydrogen ions equals the number of moles of hydroxide ions *(674)*
punto de equivalencia: punto de una valoración química en la que el número de moles de iones hidrógeno es igual al número de moles de iones hidróxido

error: the difference between the accepted value and the experimental value *(65)*
error: diferencia entre el valor aceptado y el valor experimental

ester: a derivative of a carboxylic acid in which the —OH of the carboxyl group has been replaced by the —OR from an alcohol; the general formula is RCOOR *(819)*
éster: derivado de un ácido carboxílico en el que el —OH del grupo carboxilo ha sido sustituido por el —OR de un alcohol; la fórmula general es RCOOR

ether: an organic compound in which oxygen is bonded to two carbon groups; the general formula is R—O—R *(810)*
éter: compuesto orgánico en el que el oxígeno está unido a dos grupos carbono; la fórmula general es R—O—R

evaporation: vaporization that occurs at the surface of a liquid that is not boiling *(426)*
evaporación: vaporización que se da en la superficie de un líquido que no está en ebullición

excess reagent: a reagent present in a quantity that is more than sufficient to react with a limiting reagent; any reactant that remains after the limiting reagent is used up in a chemical reaction *(401)*
reactivo excesivo: reactivo que está presente en una cantidad más que suficiente para reaccionar con un reactivo limitante; cualquier reactante que queda después de que se ha usado todo el reactivo limitante en una reacción química

exothermic process: a process that releases heat to its surroundings *(557)*
proceso exotérmico: proceso en el que se desprende calor hacia el entorno

experiment: a repeatable procedure that is used to test a hypothesis *(16)*
experimento: procedimiento repetido que sirve para probar una hipótesis

experimental value: a quantitative value measured during an experiment *(65)*
valor experimental: valor cuantitativo que se mide durante un experimento

extensive property: a property that depends on the amount of matter in a sample *(34)*
propiedad extensiva: propiedad que depende de la cantidad de materia en una muestra

F

fatty acid: the name given to continuous-chain carboxylic acids that were first isolated from fats *(816)*
ácido graso: nombre que se da a los ácidos carboxílicos de cadena continua que se aislaron originalmente de las grasas

fermentation: the production of ethanol from sugars by the action of yeast or bacteria *(807)*
fermentación: producción de etanol a partir de azúcares por la acción de levaduras o bacterias

filtration: a process that separates a solid from the liquid in a heterogeneous mixture *(40)*
filtración: proceso para separar un sólido de un líquido en una mezcla heterogénea

first-order reaction: a reaction in which the reaction rate is proportional to the concentration of only one reactant *(605)*
reacción de primer orden: reacción cuya velocidad de reacción es proporcional a la concentración de un solo reactante

fission: the splitting of a nucleus into smaller fragments, accompanied by the release of neutrons and a large amount of energy *(888)*
fisión: división de un núcleo en fragmentos más pequeños, acompañada por desprendimiento de neutrones y una gran cantidad de energía

formula unit: the lowest whole-number ratio of ions in an ionic compound; in magnesium chloride, the ratio of magnesium ions to chloride ions is 1:2 and the formula unit is $MgCl_2$ *(202)*
unidad de fórmula: razón más baja, expresada en números enteros, de los iones de un compuesto iónico; en el cloruro de magnesio, la razón de iones magnesio a iones cloruro es de 1:2, así que la unidad de fórmula es $MgCl_2$

free energy: the energy available to do work *(627)*
energía libre: energía que está disponible para realizar trabajo

freezing point: the temperature at which a liquid changes to a solid *(431)*
punto de congelación: temperatura a la cual un líquido se convierte en un sólido

freezing-point depression: the difference in temperature between the freezing point of a solution and the freezing point of the pure solvent *(536)*
disminución del punto de congelación: diferencia de temperatura entre el punto de congelación de una solución y el del disolvente puro

frequency (ν): the number of wave cycles that pass a given point per unit of time; frequency and wavelength are inversely proportional to each other *(138)*
frecuencia (ν): número de ciclos de onda que pasan por un punto específico en la unidad de tiempo; la frecuencia y la longitud de onda son inversamente proporcionales

Glossary **R127**

fuel cell: a voltaic cell that does not need to be recharged; the fuel is oxidized to produce a continuous supply of electrical energy *(734)*

celda de combustible: celda voltaica que no necesita recargarse; el combustible se oxida para producir un suministro continuo de energía eléctrica

functional group: a specific arrangement of atoms in an organic compound that is capable of characteristic chemical reactions; the chemistry of an organic compound is determined by its functional groups *(798)*

grupo funcional: distribución específica de átomos en un compuesto orgánico que puede participar en reacciones químicas características; la química de un compuesto orgánico está determinada por sus grupos funcionales

fusion: the process of combining nuclei to produce a nucleus of greater mass *(891)*

fusión: proceso en el que se combinan núcleos para producir un núcleo con mayor masa

G

gamma ray: a high-energy photon emitted by a radioisotope *(879)*

rayo gamma: fotón de alta energía emitido por un radioisótopo

gas: a form of matter that takes the shape and volume of its container; a gas has no definite shape or volume *(37)*

gas: estado de la materia que adopta la forma y el volumen del recipiente que la contiene; los gases no tienen forma ni volumen definidos

gas pressure: results from the force exerted by a gas per unit surface area of an object; due to collisions of gas particles with the object *(421)*

presión de gas: resultado de la fuerza que ejerce un gas por unidad de área total de un objeto; se debe a los choques de las partículas de gas contra el objeto

Gay-Lussac's law: the pressure of a gas is directly proportional to the Kelvin temperature if the volume is constant *(460)*

ley de Gay-Lussac: la presión de un gas es directamente proporcional a su temperatura Kelvin si se mantiene constante el volumen

gene: a segment of DNA that codes for a single peptide chain *(856)*

gen: segmento de ADN que contiene el código para una sola cadena péptida

glass: transparent fusion product of inorganic materials that have cooled to a rigid state without crystallizing *(434)*

vidrio: producto transparente que resulta de la fusión de materiales inorgánicos que se han enfriado hasta solidificarse sin cristalizarse

Graham's law of effusion: the rate of effusion of a gas is inversely proportional to the square root of its molar mass; this relationship is also true for the diffusion of gases *(472)*

ley de efusión de Graham: la velocidad de efusión de un gas es inversamente proporcional a la raíz cuadrada de su masa molar; esta relación también se cumple en la difusión de gases

gram (g): a metric mass unit equal to the mass of 1 cm^3 of water at 4°C *(77)*

gramo (g): unidad métrica de masa equivalente a la masa de 1 cm^3 de agua a 4°C

ground state: the lowest possible energy of an atom described by quantum mechanics *(145)*

estado fundamental: energía más baja que puede tener un átomo descrito por la mecánica cuántica

group: a vertical column of elements in the periodic table; the constituent elements of a group have similar chemical and physical properties *(47)*

grupo: columna vertical de elementos en la tabla periódica; los elementos de un grupo tienen propiedades físicas y químicas similares

H

half-cell: the part of a voltaic cell in which either oxidation or reduction occurs; it consists of a single electrode immersed in a solution of its ions *(730)*

semicelda: parte de una celda voltaica en la que se lleva a cabo la oxidación o reducción; consta de un solo electrodo sumergido en una solución de sus iones

half-life ($t_{1/2}$): the time required for one-half of the nuclei of a radioisotope sample to decay to products *(882)*

semivida ($t_{1/2}$): tiempo que tarda en desintegrarse la mitad de los núcleos de una muestra de un radioisótopo

half-reaction: an equation showing either the oxidation or the reduction that takes place in a redox reaction *(712)*

semirreacción: ecuación que muestra la oxidación o bien la reducción que se da en una reacción redox

half-reaction method: a method of balancing a redox equation by balancing the oxidation and reduction half-reactions separately before combining them into a balanced redox equation *(712)*

método de semirreacción: método para balancear una ecuación redox equilibrando por separado las semirreacciones de oxidación y reducción antes de combinarlas para obtener una ecuación redox balanceada

halide ion: a negative ion formed when a halogen atom gains an electron *(199)*

ion haluro: ion negativo que se forma cuando un átomo de halógeno gana un electrón

R128 Glossary

halocarbon: any member of a class of organic compounds containing covalently bonded fluorine, chlorine, bromine, or iodine *(800)*
compuesto halocarbonado: cualquier miembro de una clase de compuestos orgánicos que contienen flúor, cloro, bromo o yodo unidos mediante enlaces covalentes

halogen: a nonmetal in Group 7A of the periodic table *(167)*
halógeno: no metal del grupo 7A de la tabla periódica

heat (*q*): energy that transfers from one object to another because of a temperature difference between the objects *(556)*
calor (*q*): energía que fluye de un objeto a otro debido a la diferencia de temperatura entre los objetos

heat capacity: the amount of heat needed to increase the temperature of an object exactly 1°C *(559)*
capacidad calorífica: cantidad de calor necesaria para elevar exactamente 1°C la temperatura de un objeto

heat of combustion: the heat of reaction for the complete burning of one mole of a substance *(568)*
calor de combustión: calor de reacción al quemarse totalmente un mol de una sustancia

heat of reaction: the enthalpy change for a chemical equation exactly as it is written *(565)*
calor de reacción: cambio de entalpía correspondiente a una ecuación química en la forma exacta en que está escrita

Heisenberg uncertainty principle: it is impossible to know exactly both the velocity and the position of a particle at the same time *(148)*
principio de incertidumbre de Heisenberg: es imposible conocer con exactitud la velocidad y la posición de una partícula al mismo tiempo

Henry's law: at a given temperature the solubility of a gas in a liquid is directly proportional to the pressure of the gas above the liquid *(523)*
ley de Henry: a una temperatura determinada, la solubilidad de un gas en un líquido es directamente proporcional a la presión del gas sobre el líquido

hertz (Hz): the unit of frequency, equal to one cycle per second *(138)*
hertz (Hz): unidad de frecuencia, equivalente a un ciclo por segundo

Hess's law of heat summation: if you add two or more thermochemical equations to give a final equation, then you also add the heats of reaction to give the final heat of reaction *(578)*
ley de Hess de la suma de los calores: ley según la cual, si se suman dos o más ecuaciones termoquímicas para obtener una ecuación final, también se suman los calores de reacción para obtener el calor de reacción final

heterogeneous mixture: a mixture that is not uniform in composition; components are not evenly distributed throughout the mixture *(39)*
mezcla heterogénea: mezcla cuya composición no es uniforme; sus componentes no están distribuidos de forma equitativa en toda la mezcla

homogeneous mixture: a mixture that is uniform in composition; components are evenly distributed and not easily distinguished *(39)*
mezcla homogénea: mezcla cuya composición es uniforme; sus componentes están distribuidos de forma equitativa y no es fácil distinguirlos

homologous series: a group of compounds in which there is a constant increment of change in molecular structure from one compound in the series to the next *(765)*
serie homóloga: grupo de compuestos en el que se observa un incremento constante de cambio en la estructura molecular de un compuesto al siguiente

Hund's rule: electrons occupy orbitals of the same energy in a way that makes the number or electrons with the same spin direction as large as possible *(134)*
regla de Hund: los electrones ocupan orbitales de la misma energía haciendo que el número de electrones cuyo espín tiene la misma dirección sea lo más grande posible

hybridization: the mixing of several atomic orbitals to form the same total number of equivalent hybrid orbitals *(244)*
hibridización: combinación de varios orbitales atómicos para formar el mismo número total de orbitales híbridos equivalentes

hydrate: a compound that has a specific number of water molecules bound to each formula unit *(498)*
hidrato: compuesto que tiene un número específico de moléculas de agua unidas a cada unidad de fórmula

hydration reaction: a reaction in which water is added to an alkene *(808)*
reacción de hidratación: reacción en la que se añade agua a un alqueno

hydrocarbon: an organic compound that contains only carbon and hydrogen *(762)*
hidrocarburo: compuesto orgánico que contiene sólo carbono e hidrógeno

hydrogenation reaction: a reaction in which hydrogen is added to a carbon–carbon double bond to give an alkane *(809)*
reacción de hidrogenación: reacción en la que se añade hidrógeno a un doble enlace carbono–carbono para obtener un alcano

Glossary **R129**

hydrogen bonds: attractive forces in which a hydrogen covalently bonded to a very electronegative atom is also weakly bonded to an unshared electron pair of another electronegative atom *(251)*

enlaces de hidrógeno: fuerzas de atracción en las que un átomo de hidrógeno, unido por un enlace covalente a un átomo muy electronegativo, también se une débilmente a un par no compartido de electrones de otro átomo electronegativo

hydrogen-ion acceptor: a base, according to the Brønsted-Lowry theory; ammonia acts as a base when it accepts hydrogen ions from water *(649)*

receptor de iones hidrógeno: una base, según la teoría de Brønsted-Lowry; el amoniaco actúa como base cuando acepta iones hidrógeno del agua

hydrogen-ion donor: an acid, according to the Brønsted-Lowry theory *(649)*

donador de iones hidrógeno: un ácido, según la teoría de Brønsted-Lowry

hydronium ion (H_3O^+): the positive ion formed when a water molecule gains a hydrogen ion *(647)*

ion hidronio (H_3O^+): ion positivo que se forma cuando una molécula de agua gana un ion hidrógeno

hydroxy group: the —OH functional group in alcohols *(804)*

grupo hidroxilo: el grupo funcional —OH de los alcoholes

hygroscopic: a term describing salts and other compounds that remove moisture from the air *(499)*

higroscópico: se llama así a las sales y otros compuestos que absorben humedad del aire

hypothesis: a proposed explanation for an observation *(16)*

hipótesis: explicación propuesta para una observación

I

ideal gas constant: the constant in the ideal gas law with the symbol R and the value 8.31 (L · kPa)/(K · mol) *(465)*

constante del gas ideal: constante de la ley del gas ideal; se representa con el símbolo R y tiene un valor de 8.31 (L · kPa)/(K · mol)

ideal gas law: the relationship $PV = nRT$, which describes the behavior of an ideal gas *(465)*

ley del gas ideal: relación $PV = nRT$, que describe el comportamiento del gas ideal

immiscible: describes liquids that are insoluble in one another; oil and water are immiscible *(521)*

inmiscible: se dice de los líquidos que son insolubles uno en el otro; el aceite y el agua son inmiscibles

independent variable: the variable that is changed during an experiment; also called manipulated variable *(16)*

variable independiente: variable que cambia durante un experimento; también se llama variable manipulada

inhibitor: a substance that interferes with the action of a catalyst *(601)*

inhibidor: sustancia que interfiere la acción de un catalizador

inner transition metal: an element in the lanthanide or actinide series; the highest occupied *s* sublevel and nearby *f* sublevel of its atoms generally contain electrons; also called inner transition element *(172)*

metal de transición interna: elemento de las series de los lantánidos o los actínidos; el subnivel *s* más alto ocupado y el subnivel *f* cercano de sus átomos contienen electrones; también se llama elemento de transición interna

inorganic chemistry: the study of substances that, in general, do not contain carbon *(3)*

química inorgánica: estudio de sustancias que, en general, no contienen carbono

intensive property: a property that depends on the type of matter in a sample, not the amount of matter *(34)*

propiedad intensiva: propiedad que depende del tipo de materia de una muestra, no de la cantidad de materia

intermediate: a product of one of the steps in a reaction mechanism; it becomes a reactant in the next step *(607)*

intermediario: producto de uno de los pasos de un mecanismo de reacción; se convierte en reactante en el siguiente paso

International System of Units (SI): the revised version of the metric system, adopted by international agreement in 1960 *(74)*

Sistema Internacional de Unidades (SI): versión modificada del sistema métrico, adoptada por acuerdo internacional en 1960

ion: an atom or group of atoms that has a positive or negative charge *(176)*

ion: átomo o grupo de átomos que tiene carga positiva o negativa

ionic bond: the electrostatic attraction that binds oppositely charged ions together *(201)*

enlace iónico: atracción electrostática que une a iones con carga opuesta

ionic compound: a compound composed of positive and negative ions *(201)*

compuesto iónico: compuesto formado por iones positivos y negativos

ionization energy: the energy required to remove an electron from an atom in its gaseous state *(177)*

energía de ionización: energía necesaria para sacar un electrón de un átomo en su estado gaseoso

ionizing radiation: radiation with enough energy to knock electrons off some atoms of a bombarded substance to produce ions *(894)*

radiación ionizante: radiación que tiene la energía suficiente para desprender electrones de algunos átomos de una sustancia bombardeada, produciendo así iones

R130 Glossary

ion-product constant for water (K_w): the product of the concentrations of hydrogen ions and hydroxide ions in water; it is 1×10^{-14} at 25°C *(654)*
constante de producto iónico del agua (K_w): producto de las concentraciones de iones hidrógeno y de iones hidróxido del agua; es 1×10^{-14} a 25°C

isomers: compounds that have the same molecular formula but different molecular structures *(775)*
isómeros: compuestos que tienen la misma fórmula molecular, pero diferentes estructuras moleculares

isotopes: atoms of the same element that have the same atomic number but different atomic masses due to a different number of neutrons *(114)*
isótopos: átomos del mismo elemento que tienen el mismo número atómico pero diferentes masas atómicas porque tienen un distinto número de neutrones

J

joule (J): the SI unit of energy; 4.184 J equal one calorie *(77)*
julio (J): unidad de energía en el SI; 4.184 J equivalen a una caloría

K

Kelvin scale: the temperature scale in which the freezing point of water is 273 K and the boiling point is 373 K; 0 K is absolute zero *(78)*
escala Kelvin: escala de temperatura en la que el punto de congelación del agua es 273 K, y el de ebullición, 373 K; 0 K es el cero absoluto

ketone: an organic compound in which the carbon of the carbonyl group is joined to two other carbons; the general formula is RCOR *(812)*
cetona: compuesto orgánico en el que el carbono del grupo carbonilo está unido a otros dos carbonos: la fórmula general es RCOR

kilogram (kg): the mass of 1 L of water at 4°C; it is the base unit of mass in SI *(77)*
kilogramo (kg): masa de 1 L de agua a 4°C; es la unidad base de masa en el SI

kinetic energy: the energy an object has because of its motion *(420)*
energía cinética: energía que tienen los objetos de acuerdo con su movimiento

kinetic theory: a theory explaining the states of matter, based on the concept that all matter consists of tiny particles that are in constant motion *(420)*
teoría cinética: teoría que explica los estados de la materia basándose en el concepto de que toda la materia está formada por pequeñas partículas que están en constante movimiento

L

law of conservation of energy: in any chemical or physical process, energy is neither created nor destroyed *(557)*
ley de conservación de la energía: ley según la cual en ningún proceso químico o físico se crea ni se destruye energía

law of conservation of mass: in any physical change or chemical reaction, mass is conserved; mass can be neither created nor destroyed *(50)*
ley de conservación de la masa: en cualquier cambio físico o reacción química, la masa se conserva; la masa no puede crearse ni destruirse

law of definite proportions: in samples of any chemical compound, the masses of the elements are always in the same proportion *(289)*
ley de las proporciones definidas: en muestras de cualquier compuesto químico, las masas de los elementos siempre están en la misma proporción

law of disorder: it is a natural tendency of systems to move in the direction of maximum chaos or disorder *(630)*
ley del desorden: tendencia natural de los sistemas a desplazarse en la dirección hacia el máximo caos o desorden

law of multiple proportions: whenever two elements form more than one compound, the different masses of one element that combine with the same mass of the other element are in the ratio of small whole numbers *(290)*
ley de las proporciones múltiples: siempre que dos elementos forman más de un compuesto, las diferentes masas de un elemento que se combinan con la misma masa del otro elemento están en razón de números enteros pequeños

Le Châtelier's principle: when a stress is applied to a system in dynamic equilibrium, the system changes in a way that relieves the stress *(612)*
principio de Le Châtelier: cuando se aplica una tensión a un sistema que está en equilibrio dinámico, el sistema cambia a modo de aliviar dicha tensión

Lewis acid: any substance that can accept a pair of electrons to form a covalent bond *(651)*
ácido de Lewis: cualquier sustancia capaz de aceptar un par de electrones para formar un enlace covalente

Lewis base: any substance that can donate a pair of electrons to form a covalent bond *(651)*
base de Lewis: cualquier sustancia capaz de ceder un par de electrones para formar un enlace covalente

limiting reagent: any reactant that is used up first in a chemical reaction; it determines the amount of product that can be formed in the reaction *(401)*
reactivo limitante: cualquier reactante que se haya consumido primero en una reacción química; determina la cantidad de producto que se puede formar en la reacción

Glossary **R131**

lipid: a member of a large class of relatively water-insoluble organic compounds; fats, oils, and waxes are lipids *(850)*
lípido: miembro de una clase amplia de compuestos orgánicos relativamente insolubles en agua; las grasas, aceites y ceras son lípidos

liquid: a form of matter that flows, has a fixed volume, and an indefinite shape *(36)*
líquido: forma de materia que fluye; tiene volumen fijo pero forma indefinida

liter (L): the volume of a cube measuring 10 centimeters on each edge (1000 cm^3); it is the common unprefixed unit of volume in the metric system *(76)*
litro (L): volumen de un cubo cuyas aristas miden 10 centímetros cada una (1000 cm^3); es la unidad común de volumen en el sistema métrico

M

manipulated variable: *see* independent variable *(16)*
variable manipulada: *véase* variable independiente

mass: a measure of the amount of matter that an object contains; the SI base unit of mass is the kilogram *(34)*
masa: medida de la cantidad de materia contenida en un objeto; la unidad base de masa en el SI es el kilogramo

mass number: the total number of protons and neutrons in the nucleus of an atom *(113)*
número de masa: número total de protones y neutrones que contiene el núcleo de un átomo

matter: anything that has mass and occupies space *(2)*
materia: todo lo que tiene masa y ocupa espacio

measurement: a quantitative description that includes both a number and a unit *(62)*
medición: descripción cuantitativa que incluye tanto números como unidades

melting point (mp): the temperature at which a substance changes from a solid to a liquid; the melting point of water is 0°C *(431)*
punto de fusión (p.f.): temperatura a la que una sustancia cambia del estado sólido al líquido; el punto de fusión del agua es 0°C

metabolism: all the chemical reactions carried out by an organism; includes energy-producing (catabolism) reactions and energy-absorbing (anabolism) reactions *(863)*
metabolismo: todas las reacciones químicas llevadas a cabo por los organismos; incluyen reacciones que producen energía (catabolismo) y reacciones que consumen energía (anabolismo)

metal: one of a class of elements that are good conductors of heat and electric current; metals tend to be ductile, malleable, and shiny *(165)*
metal: miembro de una clase de elementos que son buenos conductores del calor y la electricidad; los metales suelen ser dúctiles, maleables y brillantes

metallic bond: the force of attraction that holds metals together; it consists of the attraction of free-floating valence electrons for positively charged metal ions *(209)*
enlace metálico: fuerza de atracción que mantiene unidos los átomos de un metal; se debe a la atracción entre los electrones de valencia, que flotan libremente, y los iones metálicos de carga positiva

metalloid: an element that tends to have properties that are similar to those of metals and nonmetals *(166)*
metaloide: elemento cuyas propiedades son similares a las de los metales y de los no metales

meter (m): the base unit of length in SI *(75)*
metro (m): unidad base de longitud en el SI

miscible: describes liquids that dissolve in one another in all proportions *(521)*
miscible: se les llama así a los líquidos que se disuelven uno en el otro en todas las proporciones

mixture: a physical blend of two or more substances that are not chemically combined *(38)*
mezcla: incorporación física de dos o más sustancias que no se combinan químicamente

model: a representation of an object or event *(16)*
modelo: representación de un objeto o evento

molal boiling-point elevation constant (K_b): the change in boiling point for a 1-molal solution of a nonvolatile molecular solute *(543)*
constante molal de la elevación del punto de ebullición (K_b): cambio en el punto de ebullición de una solución 1-molal de un soluto molecular no volátil

molal freezing-point depression constant (K_f): the change in freezing point for a 1-molal solution of a nonvolatile molecular solute *(542)*
constante molal de la disminución del punto de congelación (K_f): cambio en el punto de congelación de una solución 1-molal de un soluto molecular no volátil

molality (m): the concentration of solute in a solution expressed as the number of moles of solute dissolved in 1 kilogram (1000 g) of solvent *(538)*
molalidad (m): concentración de soluto en una solución expresada como el número de moles de soluto disueltos en 1 kilogramo (1000 g) de disolvente

molar heat of condensation (ΔH_{cond}): the amount of heat released by one mole of a vapor as it condenses to a liquid at a constant temperature *(572)*
calor molar de condensación (ΔH_{cond}): cantidad de calor que un mol de vapor desprende al condensarse, convirtiéndose en líquido, a temperatura constante

molar heat of fusion (ΔH_{fus}): the amount of heat absorbed by one mole of a solid substance as it melts to a liquid at a constant temperature *(569)*
calor molar de fusión (ΔH_{fus}): cantidad de calor que un mol de una sustancia sólida absorbe al fundirse, convirtiéndose en líquido, a temperatura constante

R132 Glossary

molar heat of solidification (ΔH_{solid}): the amount of heat lost by one mole of a liquid as it solidifies at a constant temperature *(569)*
calor molar de solidificación (ΔH_{solid}): cantidad de calor que un mol de un líquido pierde al solidificarse a temperatura constante

molar heat of solution (ΔH_{soln}): the enthalpy change caused by the dissolution of one mole of a substance *(574)*
calor molar de disolución (ΔH_{soln}): cambio de calor debido a la disolución de un mol de una sustancia

molar heat of vaporization (ΔH_{vap}): the amount of heat absorbed by one mole of a liquid as it vaporizes at a constant temperature *(571)*
calor molar de vaporización (ΔH_{vap}): cantidad de calor absorbida por un mol de un líquido al evaporarse a temperatura constante

molarity (M): the concentration of solute in a solution expressed as the number of moles of solute dissolved in 1 liter of solution *(525)*
molaridad (M): concentración de soluto en una solución expresada como el número de moles de soluto disueltos en 1 litro de solución

molar mass: a term used to refer to the mass of a mole of any substance *(313)*
masa molar: término empleado para referirse a la masa de un mol de cualquier sustancia

molar volume: the volume occupied by 1 mole of a gas at standard temperature and pressure (STP); 22.4 L (320)
volumen molar: volumen ocupado por 1 mol de un gas a temperatura y presión estándar (TPE); 22.4 L

mole (mol): the amount of a substance that contains 6.02×10^{23} representative particles of that substance *(308)*
mol: cantidad de una sustancia que contiene 6.02×10^{23} partículas representativas de esa sustancia

molecular compound: a compound that is composed of molecules *(223)*
compuesto molecular: compuesto formado por moléculas

molecular formula: a chemical formula of a molecular compound that shows the kinds and numbers of atoms present in a molecule of a compound *(223)*
fórmula molecular: fórmula química de un compuesto molecular que indica los tipos y números de átomos presentes en una molécula de un compuesto

molecular orbital: an orbital that applies to the entire molecule *(240)*
orbital molecular: orbital que abarca toda la molécula

molecule: a neutral group of atoms joined together by covalent bonds *(215)*
molécula: grupo neutro de átomos unidos por enlaces covalentes

mole fraction: the ratio of the moles of solute in solution to the total number of moles of both solvent and solute *(540)*
fracción molar: razón de los moles de soluto en solución al número total de moles de disolvente y soluto

mole ratio: a conversion factor derived from the coefficients of a balanced chemical equation interpreted in terms of moles *(390)*
razón molar: factor de conversión derivado de los coeficientes de una ecuación química equilibrada interpretada en términos de moles

monatomic ion: a single atom with a positive or negative charge resulting from the loss or gain of one or more valence electrons *(264)*
ion monoatómico: un solo átomo con carga positiva o negativa debido a la pérdida o ganancia de uno o más electrones de valencia

monomer: a simple molecule that repeatedly combines to form a polymer *(822)*
monómero: molécula sencilla que se combina repetidamente para formar un polímero

monoprotic acid: any acid that contains one ionizable proton (hydrogen ion); nitric acid (HNO_3) is a monoprotic acid *(647)*
ácido monoprótico: ácido que sólo contiene un protón (ion hidrógeno) ionizable; el ácido nítrico (HNO_3) es un ácido monoprótico

monosaccharide: a carbohydrate consisting of one sugar unit; also called a simple sugar *(841)*
monosacárido: carbohidrato que consta de una sola unidad de azúcar; también llamado azúcar simple

N

net ionic equation: an equation for a reaction in solution showing only those particles that are directly involved in the chemical change *(370)*
ecuación iónica neta: ecuación de una reacción en solución que sólo muestra las partículas que intervienen directamente en el cambio químico

network solid: a solid in which all of the atoms are covalently bonded to each other *(252)*
sólido en cadena: sólido en el que todos los átomos están unidos entre sí por enlaces covalentes

neutralization reaction: a reaction in which an acid and a base react in an aqueous solution to produce a salt and water *(672)*
reacción de neutralización: reacción en la que un ácido y una base reaccionan en una solución acuosa para producir una sal y agua

Glossary **R133**

neutral solution: an aqueous solution in which the concentrations of hydrogen and hydroxide ions are equal; it has a pH of 7.0 *(653)*

solución neutral: solución acuosa en la que las concentraciones de iones hidrógeno e iones hidróxido son iguales; tiene un pH de 7.0

neutron: a subatomic particle with no charge and a mass of 1 amu; found in the nucleus of an atom *(107)*

neutrón: partícula subatómica sin carga que tiene una masa de 1 uma; se le encuentra en el núcleo de los átomos

neutron absorption: a process that decreases the number of slow-moving neutrons in a nuclear reactor; this is accomplished by using control rods made of a material such as cadmium, which absorbs neutrons *(889)*

absorción de neutrones: proceso que reduce el número de neutrones lentos en un reactor nuclear; esto se logra mediante el uso de varillas de control hechas con un material como el cadmio, que absorbe neutrones

neutron moderation: a process used in nuclear reactors to slow down neutrons so the reactor fuel captures them to continue the chain reaction *(889)*

moderación de neutrones: proceso empleado en reactores nucleares para frenar los neutrones de modo que el combustible del reactor los capture para continuar la reacción en cadena

noble gas: an element in Group 8A of the periodic table; the *s* and *p* sublevels of the highest occupied energy level are filled *(170)*

gas noble: elemento del grupo 8A de la tabla periódica; los subniveles *s* y *p* del nivel energético ocupado más alto están totalmente llenos

nonelectrolyte: a compound that does not conduct an electric current in aqueous solution or in the molten state *(496)*

no electrolito: compuesto que no conduce una corriente eléctrica en solución acuosa ni en estado fundido

nonmetal: an element that tends to be a poor conductor of heat and electric current; nonmetals generally have properties opposite to those of metals *(165)*

no metal: elemento que suele ser mal conductor del calor y la electricidad; las propiedades de los no metales generalmente son opuestas a las de los metales

nonpolar covalent bond: a covalent bond in which the electrons are shared equally by the two atoms *(247)*

enlace covalente no polar: enlace covalente en el que los dos átomos comparten equitativamente los electrones

nonspontaneous reaction: a reaction that does not favor the formation of products at the specified conditions *(628)*

reacción no espontánea: reacción que no favorece la formación de productos en las condiciones especificadas

normal boiling point: the boiling point of a liquid at a pressure of 101.3 kPa or 1 atm *(430)*

punto normal de ebullición: el punto de ebullición de un líquido a una presión de 101.3 kPa o 1 atm

nuclear force: an attractive force that acts between all nuclear particles that are extremely close together, such as protons and neutrons in a nucleus *(880)*

fuerza nuclear: fuerza de atracción que actúa entre todas las partículas nucleares que están extremadamente cerca unas de otras, como los protones y los neutrones en un núcleo

nuclear radiation: the penetrating rays and particles emitted by a radioactive source *(876)*

radiación nuclear: rayos y partículas penetrantes que una fuente radiactiva emite

nucleic acid: a polymer of ribonucleotides (RNA) or deoxyribonucleotides (DNA) found primarily in cell nuclei; nucleic acids play an important role in the transmission of hereditary characteristics, protein synthesis, and the control of cell activities *(854)*

ácido nucleico: polímero de ribonucleótidos (ARN) o desoxirribonucleótidos (ADN) que se encuentra primordialmente en el núcleo de las células; los ácidos nucleicos desempeñan un papel importante en la transmisión de las características hereditarias, en la síntesis de proteínas y en el control de las actividades celulares

nucleotide: one of the monomers that make up DNA and RNA; it consists of a nitrogen-containing base (a purine or pyrimidine), a sugar (ribose or deoxyribose), and a phosphate group *(854)*

nucleótido: uno de los monómeros que constituyen el ADN y el ARN; consiste en una base nitrogenada (una purina o una pirimidina), un azúcar (ribosa o desoxirribosa) y un grupo fosfato

nucleus: the tiny, dense central portion of an atom, composed of protons and neutrons *(108)*

núcleo: la diminuta porción central densa de un átomo; se compone de protones y neutrones

O

observation: information obtained through the senses; observation in science often involves a measurement *(15)*

observación: información obtenida a través de los sentidos; en la ciencia, la observación suele implicar la medición

octet rule: atoms react by gaining or losing electrons so as to acquire the stable electron structure of a noble gas, usually eight valence electrons *(195)*

regla del octeto: los átomos reaccionan ganando o perdiendo electrones a modo de adquirir la estructura electrónica estable de un gas noble, que por lo regular consta de ocho electrones de valencia

R134 Glossary

organic chemistry: the study of compounds containing carbon *(3)*
química orgánica: estudio de los compuestos que contienen carbono

oxidation: a process that involves complete or partial loss of electrons or a gain of oxygen; it results in an increase in the oxidation number of an atom *(694)*
oxidación: proceso que implica la pérdida total o parcial de electrones o la ganancia de oxígeno; conduce a un aumento en el número de oxidación de un átomo

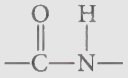
oxidation number: a positive or negative number assigned to an atom to indicate its degree of oxidation or reduction; the oxidation number of an uncombined element is zero *(701)*
número de oxidación: número positivo o negativo que se asigna a un átomo para indicar su grado de oxidación o reducción; el número de oxidación de un elemento no combinado es cero

oxidation-number-change method: a method of balancing a redox equation by comparing the increases and decreases in oxidation numbers *(710)*
método de cambio del número de oxidación: método para balancear una ecuación redox comparando los incrementos y reducciones de los números de oxidación

oxidation-reduction reaction: a reaction that involves the transfer of electrons between reactants *(693)*
reacción de oxidación–reducción: reacción en la que hay transferencia de electrones entre los reactantes

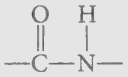
oxidizing agent: the substance in a redox reaction that accepts electrons; in the reaction, the oxidizing agent is reduced *(695)*
agente oxidante: en una reacción redox, la sustancia que acepta electrones; en la reacción, el agente oxidante se reduce

P



partial pressure: the contribution each gas in a mixture of gases makes to the total pressure *(469)*
presión parcial: contribución de cada gas de una mezcla de gases a la presión total

pascal (Pa): the SI unit of pressure *(422)*
pascal (Pa): unidad de presión en el SI



Pauli exclusion principle: an atomic orbital may describe at most two electrons, each with opposite spin direction *(134)*
principio de exclusión de Pauli: orbital atómico puede describir como máximo a dos electrones, los cuales deben tener espín opuesto

peptide: an organic compound formed by a combination of amino acids in which the amino group of one acid is united with the carboxyl group of another through an amide bond *(845)*
péptido: compuesto orgánico formado por la combinación de aminoácidos de modo que el grupo amino de un ácido se une al grupo carboxilo de otro creando un enlace amida

peptide bond: the bond between the carbonyl group of one amino acid and the nitrogen of the next amino acid in the peptide chain; the structure is

(845)
enlace péptido: enlace que hay entre el grupo carbonilo de un aminoácido y el nitrógeno del siguiente aminoácido de la cadena péptida; la estructura es

percent composition: the percent by mass of each element in a compound *(325)*
composición porcentual: porcentaje en masa de cada elemento de un compuesto

percent error: the percent that a measured value differs from the accepted value *(65)*
error porcentual: porcentaje en que un valor medido difiere del valor aceptado

percent yield: the ratio of the actual yield to the theoretical yield for a chemical reaction expressed as a percentage; a measure of the efficiency of a reaction *(405)*
rendimiento porcentual: razón del rendimiento real al rendimiento teórico de una reacción química, expresado como porcentaje; es una medida de la eficiencia de la reacción

period: a horizontal row of elements in the periodic table *(46)*
periodo: fila horizontal de elementos en la tabla periódica

periodic law: when the elements are arranged in order of increasing atomic number, there is a periodic repetition of their physical and chemical properties *(162)*
ley periódica: si los elementos se acomodan en orden de menor a mayor número atómico, se observa una repetición periódica de sus propiedades físicas y químicas

periodic table: an arrangement of elements in which the elements are separated into groups based on a set of repeating properties *(46)*
tabla periódica: distribución de los elementos dividiéndolos en grupos según un conjunto de propiedades repetidas

Glossary **R135**

pH: a number used to denote the hydrogen-ion concentration, or acidity, of a solution; it is the negative logarithm of the hydrogen-ion concentration of a solution *(656)*

pH: número empleado para denotar la concentración de ion hidrógeno (acidez) de una solución; es el logaritmo negativo de la concentración de ion hidrógeno en una solución

phase: any part of a sample with uniform composition and properties *(39)*

fase: cualquier parte de una muestra que tiene composición y propiedades uniformes

phase diagram: a graph showing the conditions at which a substance exists as a solid, liquid, or vapor *(438)*

diagrama de fases: gráfica que muestra las condiciones en las que una sustancia existe como sólido, líquido o vapor

phospholipid: a lipid that contains a phosphate group; because phospholipids have hydrophilic heads and hydrophobic tails, they form the lipid bilayers found in cell membranes *(851)*

fosfolípido: lípido que contiene un grupo fosfato; como los fosfolípidos tienen una cabeza hidrofílica y una cola hidrofóbica, pueden formar las bicapas lípidas de las membranas celulares

photoelectric effect: the ejection of electrons by certain metals when they absorb light with a frequency above a threshold frequency *(143)*

efecto fotoeléctrico: liberación de electrones por algunos metales cuando absorben la luz con una frecuencia superior a un umbral (o frecuencia mínima)

photon: a quantum of light; a discrete bundle of electromagnetic energy that interacts with matter similarly to particles *(144)*

fotón: cuanto de luz; paquete discreto de energía electromagnética que interactúa con la materia de forma similar a como lo hacen las partículas

photosynthesis: the process by which green plants and algae use radiant energy from the sun to synthesize glucose from carbon dioxide and water *(839)*

fotosíntesis: proceso por el cual las plantas y algas verdes aprovechan la energía radiante del Sol para sintetizar glucosa a partir de dióxido de carbono y agua

physical change: a change during which some properties of a material change, but the composition of the material does not change *(37)*

cambio físico: cambio durante el cual se alteran algunas propiedades de un material, pero sin que se altere la composición del material

physical chemistry: the area of chemistry that deals with the mechanism, the rate, and the energy transfer that occurs when matter undergoes a change *(3)*

fisicoquímica: área de la química que se relaciona con el mecanismo, la velocidad y la transferencia de energía que ocurre cuando la materia sufre un cambio

physical property: a quality or condition of a substance that can be observed or measured without changing the substance's composition *(35)*

propiedad física: cualidad o condición de una sustancia que se puede observar o medir sin alterar la composición de la sustancia

pi bond (π bond): a covalent bond in which the bonding electrons are most likely to be found in sausage-shaped regions above and below the bond axis of the bonded atoms *(241)*

enlace pi (enlace π): enlace covalente en el que hay una alta probabilidad de encontrar los electrones de enlace en regiones alargadas que están arriba y abajo del eje de enlace de los átomos enlazados

Planck's constant (h): a number used to calculate the radiant energy (E) absorbed or emitted by a body based on the frequency of radiation (143)

constante de Planck (h): número que se usa para calcular la energía radiante (E) que un cuerpo absorbe o emite basándose en la frecuencia de radiación

polar covalent bond (polar bond): a covalent bond between atoms in which the electrons are shared unequally *(248)*

enlace covalente polar (enlace polar): enlace covalente entre átomos que no comparten equitativamente sus electrones

polar molecule: a molecule in which one side of the molecule is slightly negative and the opposite side is slightly positive *(249)*

molécula polar: molécula que tiene un lado ligeramente negativo y el otro ligeramente positivo

polyatomic ion: a tightly bound group of atoms that behaves as a unit and has a positive or negative charge *(232)*

ion poliatómico: grupo fuertemente enlazado de átomos, que se comporta como una unidad y tiene carga positiva o negativa

polymer: a very large molecule formed by the covalent bonding of repeating small molecules, known as monomers *(822)*

polímero: molécula muy grande formada por la unión, mediante enlaces covalentes, de moléculas pequeñas repetidas, llamadas monómeros

polysaccharide: a complex carbonydrate polymer formed by the linkage of many monosaccharide monomers; starch, glycogen, and cellulose are polysaccharides *(843)*

polisacárido: carbohidrato complejo formado por el encadenamiento de muchos monómeros monosacáridos; el almidón, el glucógeno y la celulosa son polisacáridos

positron: a particle with the mass of an electron but a positive charge *(881)*

positrón: partícula con la misma masa que un electrón pero con carga positiva

R136 Glossary

precipitate: a solid that forms and settles out of a liquid mixture *(49)*
precipitado: sólido que se forma a partir de una mezcla líquida y se asienta

precision: describes the closeness, or reproducibility, of a set of measurements taken under the same conditions *(64)*
precisión: cifra que describe la variabilidad de una serie de mediciones efectuadas en las mismas condiciones

product: a substance produced in a chemical reaction *(48)*
producto: sustancia que se obtiene en una reacción química

protein: any peptide with more than 100 amino acids *(845)*
proteína: cualquier péptido que tiene más de 100 aminoácidos

proton: a positively charged subatomic particle found in the nucleus of an atom *(107)*
protón: partícula subatómica con carga positiva que se encuentra en el núcleo de los átomos

pure chemistry: the pursuit of chemical knowledge for its own sake *(3)*
química pura: búsqueda de conocimientos químicos por sí mismos

pure substance: *see* substance
sustancia pura: *véase* sustancia

Q

quantum: the amount of energy needed to move an electron from one energy level to another *(129)*
cuanto: cantidad de energía necesaria para desplazar un electrón de un nivel energético a otro

quantum mechanical model: the modern description, primarily mathematical, of the behavior of electrons in atoms *(130)*
modelo según la mecánica cuántica: descripción moderna, primordialmente matemática, del comportamiento de los electrones en los átomos

R

radioactivity: the process by which nuclei emit particles and rays *(876)*
radiactividad: proceso por el cual los núcleos emiten partículas y rayos

radioisotope: an isotope that has an unstable nucleus and undergoes radioactive decay *(876)*
radioisótopo: isótopo cuyo núcleo es inestable y sufre desintegración radiactiva

rate: describes the speed of change over an interval of time *(595)*
velocidad (de reacción): cifra que describe la velocidad de cambio a lo largo de un intervalo de tiempo

rate law: an expression relating the rate of a reaction to the concentration of the reactants *(604)*
ley de velocidad de reacción: expresión que relaciona la velocidad de una reacción con la concentración de los reactantes

reactant: a substance present at the start of a reaction *(48)*
reactante: sustancia presente al principio de una reacción

reaction mechanism: a series of elementary reactions that take place during the course of a complex reaction *(607)*
mecanismo de reacción: serie de reacciones básicas que se dan durante el curso de una reacción compleja

reducing agent: the substance in a redox reaction that donates electrons; in the reaction, the reducing agent is oxidized *(695)*
agente reductor: en una reacción redox, la sustancia que cede electrones; en la reacción, el agente reductor se oxida

reduction: a process that involves a complete or partial gain of electrons or the loss of oxygen; it results in a decrease in the oxidation number of an atom *(694)*
reducción: proceso que implica una ganancia total o parcial de electrones o pérdida de oxígeno; provoca una disminución en el número de oxidación de un átomo

reduction potential: a measure of the tendency of a given half-reaction to occur as a reduction (gain of electrons) in an electrochemical cell *(737)*
potencial de reducción: medida de la tendencia que tiene una semirreacción específica de efectuarse como reducción (con ganancia de electrones) en una celda electroquímica

representative element: an element in an "A" group in the periodic table; as a group these elements display a wide range of physical and chemical properties. In their atoms, the *s* and *p* sublevels in the highest occupied energy level are partially filled *(171)*
elemento representativo: elemento de un grupo "A" de la tabla periódica; en conjunto, estos elementos exhiben una amplia gama de propiedades físicas y químicas. En sus átomos, los subniveles *s* y *p* del nivel energético ocupado más alto están parcialmente llenos

representative particle: the smallest unit into which a substance can be broken down without a change in composition, usually atoms, molecules, or ions *(308)*
partícula representativa: unidad más pequeña en que puede dividirse una sustancia sin que cambie su composición; por lo regular es un átomo, molécula o ion

resonance structure: one of the two or more equally valid electron dot structures of a molecule or polyatomic ion *(237)*
estructura de resonancia: una de las dos o más estructuras electrón-punto igualmente válidas de una molécula o ion poliatómico

responding variable: *see* dependent variable *(16)*
variable de respuesta: *véase* variable dependiente

Glossary **R137**

reversible reaction: a reaction in which the conversion of reactants into products and the conversion of products into reactants occur simultaneously *(609)*

reacción reversible: reacción en la que se da en forma simultánea la conversión de reactantes en productos y la conversión de productos en reactantes

S

salt bridge: a tube containing a strong electrolyte used to separate the half-cells in a voltaic cell; it allows the passage of ions from one half-cell to the other but prevents the solutions from mixing completely *(730)*

puente salino: tubo que contiene un electrolito fuerte y se usa para separar las semiceldas de una celda voltaica; permite el paso de iones de una semicelda a la otra, pero impide que las soluciones se mezclen totalmente

salt hydrolysis: a process in which the cations or anions of a dissociated salt accept hydrogen ions from water or donate hydrogen ions to water *(677)*

hidrólisis de sales: proceso por el cual los cationes o aniones de una sal disociada aceptan iones hidrógeno del agua o ceden iones hidrógeno al agua

saponification: the hydrolysis of fats or oils by a hot aqueous alkali-metal hydroxide; soaps are made by saponification *(851)*

saponificación: hidrólisis de grasas o aceites con una solución acuosa caliente de un hidróxido de metal alcalino; los jabones se hacen mediante la saponificación

saturated compound: an organic compound in which all carbon atoms are joined by single covalent bonds; it contains the maximum number of hydrogen atoms per carbon atom *(772)*

compuesto saturado: compuesto orgánico en el que todos los átomos de carbono están unidos unos a otros por enlaces covalentes sencillos; contiene el número máximo de átomos de hidrógeno por átomo de carbono

saturated solution: a solution containing the maximum amount of solute for a given amount of solvent at a constant temperature and pressure; an equilibrium exists between undissolved solute and ions in solution *(520)*

solución saturada: solución que contiene la cantidad máxima de soluto para una cantidad dada de disolvente a temperatura y presión constantes; existe equilibrio entre el soluto no disuelto y los iones en solución

scientific law: a concise statement that summarizes the results of many observations and experiments *(17)*

ley científica: expresión concisa que resume los resultados de muchas observaciones y experimentos

scientific method: a logical, systematic approach to the solution of a scientific problem; steps in the scientific method include making observations, testing hypotheses, and developing theories *(15)*

método científico: enfoque lógico y sistemático para resolver un problema científico; los pasos del método científico incluyen hacer observaciones, probar hipótesis y desarrollar teorías

scientific notation: an expression of numbers in the form $m \times 10^n$, where m is equal to or greater than 1 and less than 10, and n is an integer *(62)*

notación científica: convención por la cual los números se expresan en la forma $m \times 10^n$, donde m es un número mayor o igual que 1 y menor que 10, y n es un entero

self-ionization: a term describing the reaction in which two water molecules react to produce ions *(653)*

autoionización: reacción en la que dos moléculas de agua reaccionan para producir iones

sigma bond (σ bond): a bond formed when two atomic orbitals combine for form a molecular orbital that is symmetrical around the axis connecting the two atomic nuclei *(240)*

enlace sigma (enlace σ): enlace que se forma cuando dos orbitales atómicos se combinan para formar un orbital molecular que es simétrico respecto al eje que conecta a los dos núcleos atómicos

significant figures: all the digits that can be known precisely in a measurement, plus a last estimated digit *(66)*

dígitos significativos: todos los dígitos de una medición que se pueden conocer con precisión, más un último dígito estimado

single covalent bond: a bond formed when two atoms share a pair of electrons *(226)*

enlace covalente sencillo: enlace que se forma cuando dos átomos comparten un par de electrones

single-replacement reaction: a chemical change in which one element replaces a second element in a compound; also called a displacement reaction *(360)*

reacción de sustitución sencilla: cambio químico en el que un elemento reemplaza a un segundo elemento en un compuesto; también llamado reacción de desplazamiento

skeleton equation: a chemical equation that does not indicate the relative amounts of reactants and products *(348)*

ecuación esqueleto: ecuación química que no indica las cantidades relativas de los reactantes y productos

solid: a form of matter that has a definite shape and volume *(36)*

sólido: estado de la materia que tiene forma y volumen definidos

R138 Glossary

solubility: the amount of a substance that dissolves in a given quantity of solvent at specified conditions of temperature and pressure to produce a saturated solution *(520)*

solubilidad: cantidad de una sustancia que se disuelve en una cantidad dada de disolvente, bajo condiciones específicas de temperatura y presión, para producir una solución saturada

solubility product constant (K_{sp}): an equilibrium constant applied to the solubility of electrolytes; it is equal to the product of the concentrations of the ions each raised to a power equal to the coefficient of the ion in the dissociation equation *(622)*

constante del producto de solubilidad (K_{sp}): constante de equilibrio aplicada a la capacidad disoluble de electrolitos; es igual al producto de las concentraciones de los iones, cada una elevada a una potencia igual al coeficiente que tiene ese ion en la ecuación de disociación

solute: dissolved particles in a solution *(494)*

soluto: partículas disueltas en una solución

solution: a homogeneous mixture; consists of solutes dissolved in a solvent *(39)*

solución: mezcla homogénea que consiste en solutos disueltos en un disolvente

solvation: a process that occurs when an ionic solute dissolves; in solution, solvent molecules surround the positive and negative ions *(495)*

solvatación: proceso que tiene lugar cuando se disuelve un soluto iónico; en solución, las moléculas de disolvente rodean a los iones positivos y negativos

solvent: the dissolving medium in a solution *(494)*

disolvente: medio dispersor en una solución

specific heat: the amount of heat needed to increase the temperature of 1 g of a substance 1°C; also called specific heat capacity *(559)*

calor específico: cantidad de calor requerida para elevar 1°C la temperatura de 1 g de una sustancia

specific rate constant: a proportionality constant relating the concentrations of reactants to the rate of the reaction *(604)*

constante específica de velocidad de reacción: constante de proporcionalidad que relaciona las concentraciones de los reactantes con la velocidad de la reacción

spectator ion: an ion that is not directly involved in a chemical reaction; an ion that does not change oxidation number or composition during a reaction *(370)*

ion espectador: ion que no interviene directamente en una reacción química; ion que no cambia de número de oxidación ni de composición durante una reacción

spectrum: wavelengths of visible light that are separated when a beam of light passes through a prism; range of wavelengths of electromagnetic radiation *(139)*

espectro: longitudes de onda de la luz visible que se separan cuando un haz de luz atraviesa un prisma; gama de longitudes de onda de radiación electromagnética

spin: a quantum mechanical property of electrons that may be thought of as clockwise or counterclockwise *(134)*

espín: propiedad de los electrones según la mecánica cuántica en la cual la rotación se considera en sentido de las agujas del reloj o en sentido contrario a las agujas del reloj

spontaneous reaction: a reaction that favors the formation of products at the specified conditions; spontaneity depends on enthalpy and entropy changes *(628)*

reacción espontánea: reacción que favorece la formación de productos, bajo las condiciones especificadas; la espontaneidad depende de los cambios de entalpía y de entropía

standard atmosphere (atm): a unit of pressure; it is the pressure required to support 760 mm of mercury in a mercury barometer at 25°C *(422)*

atmósfera estándar (atm): unidad de presión; es la presión necesaria para sostener 760 mm de mercurio en un barómetro de mercurio a 25°C

standard cell potential (E°_{cell}): the measured cell potential when the ion concentration in the half-cells are 1.00*M* at 1 atm of pressure and 25°C *(737)*

potencial estándar de celda (E°_{cell}): potencial de celda que se mide cuando las concentraciones de los iones en las semiceldas son 1.00*M* a 1 atm de presión y 25°C

standard heat of formation (ΔH_f°): the change in enthalpy that accompanies the formation of one mole of a compound from its elements with all substances in their standard states at 25°C *(580)*

calor estándar de formación (ΔH_f°): cambio de entalpía que acompaña a la formación de un mol de un compuesto a partir de sus elementos, estando todas las sustancias en su estado estándar a 25°C

standard hydrogen electrode: an arbitrary reference electrode (half-cell) used with another electrode (half-cell) to measure the standard reduction potential of that cell; the standard reduction potential of the hydrogen electrode is assigned a value of 0.00 V *(738)*

electrodo estándar de hidrógeno: electrodo (semicelda) arbitrario de referencia que se usa junto con otro electrodo (semicelda) para medir el potencial estándar de reducción de esa celda; se asigna al potencial estándar de reducción del electrodo de hidrógeno el valor de 0.00 V

standard solution: a solution of known concentration used in carrying out a titration *(674)*

solución estándar: solución cuya concentración se conoce; se usa para efectuar valoraciones químicas

standard temperature and pressure (STP): the conditions under which the volume of a gas is usually measured; standard temperature is 0°C, and standard pressure is 101.3 kPa, or 1 atmosphere (atm) *(320)*

temperatura y presión estándar (TPE): las condiciones en las que normalmente se mide el volumen de un gas; la temperatura estándar es 0°C y la presión estándar es 101.3 kPa, o sea, 1 atmósfera (atm)

Glossary **R139**

stereoisomers: molecules that have atoms in the same order, but which differ in the arrangement of the atoms in space *(776)*

estereoisómeros: moléculas cuyos átomos están en el mismo orden, pero que difieren en la distribución de los átomos en el espacio

stoichiometry: that portion of chemistry dealing with numerical relationships in chemical reactions; the calculation of quantities of substances involved in chemical equations *(386)*

estequiometría: rama de la química que se ocupa de las relaciones numéricas en las ecuaciones químicas; el cálculo de las cantidades de sustancias presentes en las ecuaciones químicas

straight-chain alkane: a saturated hydrocarbon that contains any number of carbon atoms arranged one after the other in a chain *(764)*

alcano de cadena lineal: hidrocarburo saturado que contiene cualquier número de átomos de carbono acomodados uno tras otro en una cadena

strong acid: an acid that is completely (or almost completely) ionized in aqueous solution *(664)*

ácido fuerte: ácido que se ioniza casi totalmente en solución acuosa

strong base: a base that completely dissociates into metal ions and hydroxide ions in aqueous solution *(668)*

base fuerte: base que se disocia totalmente en una solución acuosa para dar iones metálicos y iones hidróxido

strong electrolyte: a solution in which a large portion of the solute exists as ions *(497)*

electrolito fuerte: solución en la que una porción considerable del soluto existe en forma de iones

structural formula: a chemical formula that shows the arrangement of atoms in a molecule or a polyatomic ion; each dash between a pair of atoms indicates a pair of shared electrons *(227)*

fórmula estructural: fórmula química que indica la distribución de los átomos en una molécula o ion poliatómico; cada raya entre un par de átomos indica un par de electrones compartidos

sublimation: the process in which a solid changes to a gas or vapor without passing through the liquid state *(436)*

sublimación: proceso por el cual un sólido cambia a gas o vapor sin pasar por el estado líquido

substance: matter that has a uniform and definite composition; either an element or a compound; also called pure substance *(35)*

sustancia: materia que tiene una composición uniforme y definida; puede ser un elemento o un compuesto; también llamada sustancia pura

substituent: an atom or group of atoms that can take the place of a hydrogen atom on a parent hydrocarbon molecule *(767)*

sustituto: átomo o grupo de átomos que puede ocupar el lugar de un átomo de hidrógeno en una molécula precursora de hidrocarburo

substitution reaction: a common type of organic reaction; involves the replacement of an atom or group of atoms by another atom or group of atoms *(801)*

reacción de sustitución: tipo común de reacción orgánica; implica el reemplazo de un átomo o grupo de átomos por otro átomo o grupo de átomos

substrate: a molecule on which an enzyme acts *(847)*

sustrato: molécula sobre la que actúa una enzima

supersaturated solution: a solution that contains more solute than it can theoretically hold at a given temperature; excess solute precipitates if a seed crystal is added *(522)*

solución sobresaturada: solución que contiene más soluto del que en teoría puede contener a una temperatura específica; el soluto en exceso se precipita si se añade un cristal que actúa como semilla

surface tension: an inward force that tends to minimize the surface area of a liquid; it causes the surface to behave as if it were a thin skin *(490)*

tensión superficial: fuerza que tiende a reducir al mínimo la superficie total de un líquido y actúa hacia el seno de éste; hace que la superficie se comporte como si fuera una membrana elástica

surfactant: any substance that interferes with the hydrogen bonding between water molecules and thereby reduces surface tension; soaps are surfactants *(490)*

tensoactivo: cualquier sustancia que perturba la formación de enlaces de hidrógeno entre las moléculas de agua y así reduce la tensión superficial; los jabones y detergentes son tensoactivos

surroundings: everything in the universe outside of the system *(557)*

entorno: todo lo que no forma parte del sistema, es decir, el resto del universo

suspension: a mixture from which some of the particles settle out slowly upon standing *(504)*

suspensión: mezcla de la que se separan lentamente algunas partículas por asentamiento cuando no se agita

synthesis reaction: *see* combination reaction

reacción de síntesis: *véase* reacción de combinación

system: a part of the universe on which you focus your attention *(557)*

sistema: parte del universo en la que centramos nuestra atención

R140 Glossary

T

technology: the means by which a society provides its members with those things needed and desired *(8)*
tecnología: los medios por los cuales una sociedad proporciona a sus miembros las cosas que necesitan y desean

temperature: a measure of the average kinetic energy of particles in matter; temperature determines the direction of heat transfer *(78)*
temperatura: medida de la energía cinética promedio de las partículas de la materia; la temperatura determina la dirección de la transferencia de calor

tetrahedral angle: a bond angle of 109.5° that results when a central atom forms four bonds directed toward the center of a regular tetrahedron *(242)*
ángulo tetraédrico: ángulo de enlace de 109.5° que se forma cuando un átomo central forma cuatro enlaces dirigidos hacia el centro de un tetraedro regular

theoretical yield: the amount of product that could form during a reaction calculated from a balanced chemical equation; it represents the maximum amount of product that could be formed from a given amount of reactant *(405)*
rendimiento teórico: cantidad de producto que podría formarse durante una reacción, calculada a partir de una ecuación química balanceada; representa la cantidad máxima de producto que podría formarse a partir de una cantidad determinada de reactantes

theory: a well-tested explanation for a broad set of observations *(17)*
teoría: explicación, probada exhaustivamente, de un conjunto amplio de observaciones

thermochemical equation: a chemical equation that includes the enthalpy change *(565)*
ecuación termoquímica: ecuación química que incluye el cambio de calor

thermochemistry: the study of energy changes that occur during chemical reactions and changes in state *(556)*
termoquímica: estudio de los cambios de calor que acompañan a las reacciones químicas y a los cambios de estado físico

titration: process used to determine the concentration of a solution (often an acid or base) in which a solution of known concentration (the standard) is added to a measured amount of the solution of unknown concentration until an indicator signals the end point *(673)*
valoración química: proceso empleado para determinar la concentración de una solución (a menudo un ácido o base) por el cual una solución de concentración conocida (solución estándar) se añade a una cantidad medida de una solución cuya concentración se desconoce, hasta que un indicador marca el punto final

***trans* configuration:** the configuration in which substituent groups are on the opposite sides of a double bond *(776)*
configuración *trans:* configuración en la que los grupos sustitutos están en lados opuestos de un doble enlace

transition metal: one of the Group B elements in which the highest occupied *s* sublevel and a nearby *d* sublevel generally contain electrons *(172)*
metal de transición: uno de los elementos del grupo B en el que el subnivel *s* ocupado más alto y un subnivel *d* cercano generalmente contienen electrones

transmutation: the conversion of an atom of one element to an atom of another element *(885)*
transmutación: conversión de un átomo de un elemento en un átomo de otro elemento

transuranium element: any elements in the periodic table with atomic number above 92, the atomic number of uranium *(886)*
elemento transuránico: cualquier elemento de la tabla periódica cuyo número atómico es mayor que 92, el número atómico del uranio

triglyceride: an ester in which all three hydroxyl groups on a glycerol molecule have been replaced by long-chain fatty acids; fats are triglycerides *(850)*
triglicérido: éster en el que los tres grupos hidroxilo de una molécula de glicerol han sido sustituidos por ácidos grasos de cadena larga; las grasas son triglicéridos

triple covalent bond: a covalent bond in which three pairs of electrons are shared by two atoms *(230)*
enlace covalente triple: enlace covalente en el que dos átomos comparten tres pares de electrones

triple point: the point on a phase diagram that represents the only set of conditions at which all three phases exist in equilibrium with one another *(402)*
punto triple: punto de un diagrama de fases que representa el único conjunto de condiciones en el que las tres fases existen en equilibrio

triprotic acid: any acid that contains three ionizable protons (hydrogen ions); phosphoric acid (H_3PO_4) is a triprotic acid (647)
ácido triprótico: ácido que contiene tres protones (iones hidrógeno) ionizables; el ácido fosfórico (H_3PO_4) es un ácido triprótico

Tyndall effect: scattering of light by particles in a colloid or suspension, which causes a beam of light to become visible *(506)*
efecto Tyndall: dispersión de la luz por las partículas de un coloide o una suspensión, que hace que un haz de luz se vuelva visible

Glossary **R141**

U

unit cell: the smallest group of particles within a crystal that retains the geometric shape of the crystal *(433)*
celda unitaria: grupo más pequeño de partículas dentro de un cristal que conserva la forma geométrica del cristal

unsaturated solution: a solution that contains less solute than a saturated solution at a given temperature and pressure *(520)*
solución insaturada: se dice de una solución que contiene menos soluto que una solución saturada a una temperatura y presión específicas

unsaturated compound: an organic compound with one or more double or triple carbon–carbon bonds *(772)*
compuesto insaturado: compuesto orgánico que tiene uno o más dobles o triples enlaces carbono–carbono

unshared pair: a pair of valence electrons that is not shared between atoms *(227)*
par no compartido: par de electrones de valencia que no es compartido por dos átomos

V

vacuum: a space where no particles of matter exist *(421)*
vacío: espacio en el que no existen partículas de materia

valence electron: an electron in the highest occupied energy level of an atom *(194)*
electrón de valencia: electrón que está en el nivel energético ocupado más alto de un átomo

van der Waals forces: the two weakest intermolecular attractions—dispersion interactions and dipole forces *(250)*
fuerzas de van der Waals: las dos atracciones intermoleculares más débiles—interacciones de dispersión y fuerzas dipolares

vapor: describes the gaseous state of a substance that is generally a liquid or solid at room temperature *(37)*
vapor: estado gaseoso de una sustancia que suele ser líquida o sólida a temperatura ambiente

vaporization: the conversion of a liquid to a gas or a vapor *(426)*
vaporización: conversión de un líquido en gas o vapor

vapor pressure: a measure of the force exerted by a gas above a liquid in a sealed container; a dynamic equilibrium exists between the vapor and the liquid *(427)*
presión de vapor: medida de la fuerza que ejerce un gas sobre un líquido en un contenedor sellado; equilibrio dinámico que existe entre el vapor y el líquido

voltaic cell: an electrochemical cell used to convert chemical energy into electrical energy; the energy is produced by a spontaneous redox reaction *(730)*
celda voltaica: celda electroquímica empleada para convertir energía química en energía eléctrica; la energía se produce por una reacción redox espontánea

volume: a measure of the space occupied by a sample of matter *(34)*
volumen: medida del espacio ocupado por una muestra de materia

VSEPR theory: valence-shell electron-pair repulsion theory; because electron pairs repel, molecules adjust their shapes so that valence electron pairs are as far apart as possible *(242)*
teoría RPENV: teoría de repulsión de pares de electrones del nivel de valencia; como los pares de electrones se repelen, las moléculas ajustan su forma de modo que los pares de electrones de valencia estén lo más alejados posible entre sí

W

water of hydration: water molecules that are an integral part of a crystal structure *(498)*
agua de hidratación: moléculas de agua que forman parte integral de una estructura cristalina

wavelength (λ): the distance between adjacent crests of a wave *(138)*
longitud de onda (λ): distancia entre crestas adyacentes de una onda

wax: an ester of a long-chain fatty acid and a long-chain alcohol *(852)*
cera: éster de un ácido graso de cadena larga y un alcohol de cadena larga

weak acid: an acid that is only slightly ionized in aqueous solution *(664)*
ácido débil: ácido que se ioniza poco en solución acuosa

weak base: a base that reacts with water to form the hydroxide ion and the conjugate acid of the base *(668)*
base débil: base que reacciona con agua para formar el ion hidróxido y el ácido combinado de la base

weak electrolyte: a solution that conducts electricity poorly because only a fraction of the solute exists as ions *(497)*
electrolito débil: solución que apenas conduce la electricidad porque sólo una fracción del soluto existe en forma de iones

weight: a force that measures the pull of gravity on a given mass *(77)*
peso: fuerza que mide la atracción de la gravedad sobre una masa específica

R142 Glossary

Index

The page on which a term is defined is indicated in **boldface** type. Page numbers for appendices begin with *R*.

A

absolute zero **79**
absorption, neutron 889
accepted value **65**
accuracy **64,** 72
acetone 813
acetylene 245, 330, 568, R15
acid-base indicators 660–661
acid-base reactions 672
acid-base titrations 673, 677
acid dissociation constant (K_a) **665**–666
acidic solutions **654**
acid rain R23
acids **285,** 646, 654, 669
  aqueous solutions of 646
  Arrhenius 647
  Brønsted-Lowry 649–651
  common 286, 647, 664
  conjugate 650
  names and formulas of 285–287
  Lewis 651
  reactions between bases and 379
  strong 664
  weak 664
actinides 189
activated complex **596**
activation energy **596**
  effect of catalyst on 601
active site **847**
activity series **361,** 729
actual yield **405**
addition polymers 822–824
addition reactions **807**–809
adenine 854
adenosine diphosphate (ADP) 862–863
adenosine triphosphate (ATP) **862**
adsorption 506
aerosol can, pressure of gas in 453
agriculture, 663, 860, 866
agronomist 663
air bags 397, 450, 451
alanine 845, 857
alchemy 14–15
alcohols **804**–807
  aliphatic 805
  denatured 807
  ethyl 805
  general formula for 804–805
  naming 805
  properties of 806
  uses of 806–807
aldehydes **812**–814, 818
  properties of 814
  testing for 818
  uses of 813
algal blooms 270
aliphatic compounds **780**
alkali metals **167,** 360, R2
alkaline battery 733
alkaline earth metals **167**
alkanes **764**
  arrangements of carbon atoms in 764–771
  branched-chain 767–768
  drawing structural formulas for 767
  straight-chain 764–765
alkenes **772**
alkyl group **768**
alkyl halide **800**
alkynes 773
allotropes 433, **434**
alloys **211**–212
alpha emission 881
alpha particles 108, **877**
alpha radiation 877
altitude, boiling point and 429
aluminum 164, 264
  alloys of 211
  anodized R13
  atomic number for 167
  manufacturing R13
  properties of 35, R10
  recycling R12
  specific heat of 559
amazonite 433
americium 189
amide bonds 826
amines **811,** 826
amino acids **844**
  common 845
  DNA code words for 857
  general structure of 844
ammonia 223, 232, 649, R22
  electron dot structure for 228
  in fuel cells 735
  nitrogen in 242
  relative strength of 664
  uses of 668
ammonia fertilizers 232
ammonium cation 268
ammonium chloride 678
ammonium nitrate, dissolution of 574
amorphous solid **434**
amphoteric **651**
amplitude **138**
anabolism **864**
analytical chemistry 2, **3**
andalusite R14
anhydrous **498**
anions **176,** 265
  formation of 198–199, 265
  names of 265, 267
anode **730,** 744
anthracite 785
antifreeze 537
antimony 163, R20, R21
applied chemistry **3**
aquamarine 716
aqueous solutions **494,** 653
  of acids 646
  freezing-point depression of 536
  reactions in 369–373
  simple sugars in 842
aragonite 204
arginine 845
argon 170, R32, R33
aromatic compounds **780**
  substituted 781
aromatic hydrocarbons 780–781
Arrhenius, Svante 646
Arrhenius acids 647
Arrhenius bases 648
arsenic 161, R20
arsenic trioxide R21
arsenide ion 265
arson investigator 774
aryl halide **800**
asparagine 845
aspartic acid 845
asphyxiation 280
astatine R28
asymmetric carbons **776**–777, 793
atmosphere, elements in R1
atmospheric chemistry 455
atmospheric nitrogen **865**
atmospheric pressure **421**
atomic emission spectra 138–**140,** 149
atomic mass 116–119, **117,** 312, **313**
atomic mass units (amu) **116,** 312
atomic models 102–103, 128–132, 133
  Rutherford 108–109, 128, 130
atomic nucleus 107–109
atomic number **112**–113
atomic orbitals **131**–132
atomic radius **174**
atomic size, trends in 174–176
atomic spectra, explaining 144–145
atomic theory 102–103
atoms **102**
  assigning oxidation numbers to 703

Index **R143**

in chemical equations 386
converting moles to number of 311
electron arrangement in 134–137
energy levels in 128–129
identifying oxidized and reduced 705, 706
sizes of 103–104
structure of 4
Aufbau diagram 135
Aufbau principle **134,** 137
average kinetic energy 423–424
Avogadro di Quaregna, Amedeo 308, 320
Avogadro's hypothesis **320**
Avogadro's number **308,** 310, 316, 387

B

bacteria
nitrogen-fixing 865, 866
symbiotic 866
baking soda 271, 399, 566
balanced equations **350,** 386, 415
interpretation of 386, 388
as recipe 385
balers 53
band of stability **880**
barium 729, R6
barium carbonate 372
barium hydroxide, solubility of 522
barium peroxide R7
barium sulfate 495
barometer **421**
base dissociation constant (K_b) **668**
bases **287,** 646
Arrhenius 648
Brønsted-Lowry 649–651, 677
common 648, 664
conjugate 650
Lewis 651
names and formulas of 287–288
reactions between acids and 379
strong 668
weak 668
basic solutions **654**
batteries **733**–734, 744
bauxite 751, R10
Becquerel, Antoine Henri 876
bends 483
Benedict's reagents 818
benzene 780
halogenation of 801
structure of 780
benzoic acid 666
berkelium 189
beryl 204, 716
beryllium 112, R6
Berzelius, Jöns Jacob 45, R14, R24
beta emission 880
beta particle **878**
beta radiation 877, 878
binary compound **272**
binary ionic compounds 271–275
naming 274–275
writing formulas for 272–273
binary molecular compounds 280–283
naming 281–282
writing formulas for 282–283
binders in fireworks 700
biochemistry 2, **3,** 111, 853
bioplastic 1, 9
bioremediation 784
biotechnology 10
bismuth 163, R20
bituminous coal 785
black box 109
blimps 473
blood substitutes R31
Bohr, Niels 129, 133
Bohr's model 129, 130, 144–145
boiling point **428**–430, **491**
altitude and 429
calculating, for solution 544
normal 430
boiling-point elevation **537,** 540, 542–543
bond(s)
amide 826
chemical 4
covalent 223, 846
hydrogen 251
ionic 201–202
metallic 209
peptide 845
pi 241
polarity of 247–250
sigma 240–241
bond dissociation energy **236**–237
bonding 4
in metals and alloys 209–212
bonding orbital **240**
bonding theories
hybrid orbitals 244–246
molecular orbitals in 240–241
VSEPR 242–243, 763
borax R11
boric acid R11
boron 112, 212, R10
boron trifluoride 235
Bosch, Karl 609
Boyle, Robert 456
Boyle's law **456**–457
branched-chain alkanes 767–**758**
naming 769, 770
structural formulas for 770, 771
brass R38
brine, electrolysis of 748
bromine (Br_2) 160, 161, 165, 167, 251, 580, R28, R31
atomic radius 174
as diatomic element 231
properties of 35
Brønsted-Lowry acids 649–651
Brønsted-Lowry bases 649–651, 677
Brønsted-Lowry theory 649
bronze 211, R38
Brownian motion 505, **506**
bubbles 17
buckminsterfullerene (buckyball) 433, R17
buffers **678**–680, 681
Bunsen, Robert R2
burette 529
butane 223, 364, 764, 766, 782
B vitamins 848

C

cadmium R36
cadmium nitrate 628
cadmium sulfide 628
calcite 433
calcium 264, R6
calcium bromide 272
calcium carbonate 276, 289, 495, 580, 671, R9
calcium chloride 499, 535
calcium hydrogen R9
calcium hydroxide 344, 363, 649
calcium hypochlorite 693
calcium oxide R9
calcium phosphate R7
calcium sulfate 192, 499
calcium sulfate dihydrate R7
californium 189
Calorie (Cal) 558
calorie (cal) **77,** 558
calorimetry **562**–565
calorimeter **562**
constant-pressure 562
constant-volume 563
enthalpy change in 564
cancer, treatment of 897
carbohydrates **841**
classifying 841–842
general formula for 841
carbon 165, R14
allotropes of 434
asymmetric 776–777, 793
heat of combustion for 568
in the human body R1
phase diagram of R14

R144 Index

standard heat of formation of 580
carbon-14 isotope 878, 882
carbon-14 dating 903
carbon chemistry 5
carbon compounds 5
carbon cycle, energy and 839–840
carbon dioxide 83, 221, 224, 234, 310, 281, 467
double covalent bonds in 230
formula of 223, 224, 310
as greenhouse gas R18
properties of 222
solubility of 522
carbon footprints 83
carbonic acid 286, 666, 681, R9
carbon monoxide 225, 234, 259, 281, 310, R19
covalent bonding in 232
carbonyl compounds
aldehydes 812–814
carboxylic acids 815–816
esters 819–820
ketones 812–814
oxidation-reduction reactions 816–818
carbonyl group **812**
carboxyl group **815**
carboxylic acids **815**–816
careers
agronomist 663
arson investigator 774
atmospheric chemist 455
biochemist 853
chemical engineer 620
lab technician 467
meteorologist 463
sports nutrition advisor 284
carnauba wax 852
carvone 793
cast iron 212
catabolism **863**–864
catalase 848
catalysts **348,** 600–601
activation energy and 601
equilibrium and 615
catalytic converter 602–603
cathode **730,** 744
cathode ray **105**
cathode-ray tube 105
cations **176,** 264
formation of 195–197, 264
Group 1A 196
Group 2A 197
names of 264, 267
transition metal 197
cell membranes 852
cell potential **737**
cells (electrochemical) 730
electrolytic 745–751
voltaic 730–735
cells (in organisms) 838–839
function of ATP in 862–863
structure of 838–839
cellulose 843
Celsius scale **78,** 79
cesium R2, R3
cesium atomic clock R5
cesium chloride 205
cesium oxide 274
Chadwick, James 107, 133, 885
change, rates of 595
Charles, Jacques 458
Charles's law **458**–459
chemical bonds 4
chemical changes 42, **43,** 58
as chemical reactions 48
recognizing 49
chemical compounds, naming 292–294
chemical engineer 620
chemical equations 346–353, **348,** 386–389
balanced 349–353, 384–385, 386, 388, 415
coefficients in 350, 353
enthalpy change in 565
net ionic 369–371
skeleton 348–349
symbols used in 348
writing 349, 352, 359, 360, 363, 365, 371, 373
chemical equilibrium **610**
chemical formulas 46, **202**
percent composition from 327
writing 293–294
chemical potential energy **556**
chemical property **48**
chemical reactions 5, **48,** 346, 592
in aqueous solution 369–373
classes of 707
classifying 356
combination 356–357, 365
combustion 363–365, 367
decomposition 358, 366
double-replacement 362–363, 367
energy transformation in 556
enthalpy 632–633
entropy 630–633
equilibrium constants and 616–618
factors affecting equilibrium and 612–615
free energy and spontaneous 627–629
free energy change 634
macroscopic observations of 51
mass, conservation of 50
oxidation-number changes in 704–706
progress of 604–608
rate of 595 (*See also* reaction rates)
reaction mechanisms and 607–608
reversible 609–611
single-replacement 360–361, 366
solubility equilibrium and 621–626
speeding up 348
writing 347–349
chemical symbols **45**–46, 115

reasons for studying 6–7
chloramine R21
chloride ion 265
chlorine 160, 161, 167, 198, 251, 580, R28
atomic radius 174
as diatomic element 231
in fuel cells 735
isotopes of 117
in the oceans R1
properties of 35, 43
chlorine dioxide 235
chlorofluorocarbons (CFCs) R27
chloromethanes 801
chlorophyll R8
chloroplasts 839, R8
chromium 212, 716, R36, R41
cinnabar 204, 271
circulatory system 183
cis configuration **776**
cis-trans isomers **776**
citric acid ($HC_6H_7O_7$) 646
classical mechanics 147
Claude, George R33
cloning 861
cluster balloonists 448
coagulation 506
coal 785–786
cobalt R36, R40, R41
cobalt(II) chloride 498
cobalt(II) iodide 275
coefficients **350**

Index **R145**

coenzymes 848
cold pack 574
colligative properties **534**–537
  calculations involving 538–544
collision, elastic 420
collision theory **596**–597
colloids **505**–506
  properties of 507
  solutions and 519
combination reactions **356,** 366
  writing equations for 359
Combined DNA Indexing Systems (CODIS) 859
combined gas law **462**–463
combustion, heat of 568
combustion reactions **363,** 363–365, 367
common ion **624**
  finding equilibrium ion concentrations in presence of 625
common ion effect **624**–626
communication, role of, in science 19
complete ionic equation **370**
composite materials R18
compounds **42**
  aliphatic 780
  aromatic 780
  breaking down 42
  delinquescent 501
  distinguishing between elements and 42–43
  laws governing formation of 289–290
  molar mass of 314, 315
  molecular 223
  percent composition of 325–329
  properties of 43
  saturated 772
  unsaturated 772
compressibility **450**–451
concentrated solution **525**
concentration **525**–531
  determining, by titration 675
  equilibrium and 611, 612–613, 619
  reaction rates and 598
condensation 572
  molar heat of 572
condensation polymers 825–827
condensed structural formula **766**
conductivity of solutions 496
conjugate acid **650**
conjugate acid-base pair **650**
conjugate base **650**
conservation of mass 405
constitutional isomers 775
conversion factor **84**–85, 89, 328, 531
conversion problems, solving 84–85
coolant 889
coordinate covalent bonds **232**–233
coordination number **205**
copper 137, 164, R36, R38, R41
  alloys of R38
  electron configuration of 137
  oxidation of 704
  physical properties of 35
  reduction of 704
copper(II) carbonate 217
copper(II) oxide 274
corrosion 691, 697–698, 723
  controlling 698
  resistance to 697
corundum R11
Courtois, Bernard R28
covalent bonds **223,** 238, 846
  coordinate 232–233
  double 230, 237
  electron sharing in 226
  nonpolar 247
  octet rule in 226–231
  polar 248
  single 226–229
  triple 230
cracking **783**
crash test 397
cresol 805
Crick, Francis 855
crude oil 783
crystal(s) **432**
  ionic 208, 432
crystalline solids 194, 204
crystalline structure of metals 210–211
crystallization 518, 522
crystal skulls 101
crystal systems 432
cubic centimeter 76
Curie, Marie 876, R24
Curie, Pierre 876
Curie temperature R40
cyanide ion 268, 269
cyclic hydrocarbons **779**
cycloalkane **779**
cyclohexane 809
cysteine 845
cytosine 854

D

Dalton, John 45, 102–103, 133, 289, 470
  atomic theory of 103, 289, 350
  laws of definite and multiple proportions 289, 290
Dalton's law of partial pressure 469–471, **470**

Periodic Table of the Elements

PEARSON Chemistry

INDIANA

TABLE OF CONTENTS

1: Introduction to Chemistry
2: Matter and Change
3: Scientific Measurement
4: Atomic Structure
5: Electrons in Atoms
6: The Periodic Table
7: Ionic and Metallic Bonding
8: Covalent Bonding
9: Chemical Names and Formulas
10: Chemical Quantities
11: Chemical Reactions
12: Stoichiometry
13: States of Matter
14: The Behavior of Gases
15: Water and Aqueous Systems
16: Solutions
17: Thermochemistry
18: Reaction Rates and Equilibrium
19: Acids, Bases, and Salts
20: Oxidation-Reduction Reactions
21: Electrochemistry
22: Hydrocarbon Compounds
23: Functional Groups
24: The Chemistry of Life
25: Nuclear Chemistry

Sn
Tin
118.69

Chemistry doesn't just matter; it *is* matter. The air you breathe, the foods you eat, the plants you grow, the technologies you use—they all consist of matter. Chemistry describes how matter is put together and how it changes. The concepts you'll learn in this course will give you a striking awareness of the things around you and the different properties they show. For example, the oxygen in the air can corrode certain metals, such as iron. But tin, another metal, doesn't corrode as easily as iron. So you'll find tin used in things like watering cans, pails, and vintage toys. If you open a can of vegetables, you can see that the inside of the steel can is coated with tin.

Tin is just one of many elements that you encounter in your world. Each element has unique properties—properties that matter to us in one way or another, whether it's the luster of a diamond (made of carbon), the electrical conductivity of a microchip wafer (made of silicon), or the nourishing ability of nutrients in the soil (nitrogen and phosphorus). Selenium is a micronutrient found in kiwi fruit and Brazil nuts; arsenic can be used to add color to pyrotechnics and fireworks displays. As you kick off your first course in chemistry, you will quickly discover why the study of matter really matters.
